Helping You Make Informed Decisions • 1902-2002

This report was prepared by Frank Hobbs and Nicole Stoops under the general direction of John F. Long, Chief, Population Division. Numerous U.S. Census Bureau staff contributed to the data compilation, review, and publication production.

In the Population Division, Marie Pees, Chief, Census Activities and Tabulation Staff, provided key information about the availability and comparability of historical census data, as well as Census 2000 data tabulations, and Todd Gardner, Population Distribution Branch, provided significant contributions to the data compilation and understanding of the metropolitan population data. In the Housing and Household Economic Statistics Division, Leonard J. Norry, Assistant Division Chief, Jeanne Woodward, Chief, Housing Statistics Branch, and William S. Chapin, Housing Statistics Branch, provided similarly vital contributions pertaining to the housing data.

Special thanks are due to Campbell Gibson, Population Division, for his contributions to multiple phases of the production of this report. He contributed significantly to the compilation and understanding of the race and Hispanic-origin data and the households and families data. The authors are especially grateful for his thorough review of the whole report and the generous sharing of his interest in and his knowledge and breadth of understanding of historical Census Bureau data and demographic trends.

The authors are grateful to other Population Division staff for their contributions to the verification and review of the data and information contained in this report. We thank Robert A. Kominski, Assistant Division Chief, Social and Demographic Statistics, for his general direction and review, and Michael Ratcliffe, Chief, Population Distribution Branch, Jorge del Pinal, Assistant Division Chief, Special Populations, Annetta Smith, Chief, Age and Sex Statistics Branch, Gregory Spencer, Chief, Population Projections Branch, Kevin Deardorff, Chief, Ethnic and Hispanic Statistics Branch, and Claudette Bennett, Chief, Race Statistics Branch, for their review of specific chapters of the report. We thank Marjorie Hanson, Population Division, for the improvements added by her review of the complete text of the report. For verification, the authors thank Donna Defibaugh,
Andres Claudio, Marylou Unsell, and Debra Niner, Population Division.
In the Geography Division, the authors would like to thank the Cartographic Operations Branch, including Timothy Trainor, Chief, Constance Beard, Tracy Corder, and Deanna Fowler for assistance in the geographic representation of the state population data, and Frederick R. Broome for assistance with the U.S. centers of population trends.

Greg Carroll, Penny Heiston, Jan Sweeney, Elizabeth J. Williams, and Arlene Butler of the Administrative and Customer Services Division, Walter C. Odom, Chief, provided publication and printing management, graphics design, and composition and editorial review for print and electronic media. General direction and project management were provided by Gary J. Lauffer, Chief, Publication Services Branch.

Finally, the authors wish to thank the many Population Division and Housing and Household Economic Statistics Division staff, both past and present, whose subject matter contributions to each decennial census of the 20th century helped make the production of this report possible.

## HIGHLIGHTS

## Population Size and Geographic Distribution

The U.S. population more than tripled from 76 million people in 1900 to 281 million people in 2000 . The growth of 32.7 million people in the 1990 s represented the largest numerical increase of any decade in U.S. history.

The U.S. population grew increasingly metropolitan each decade, from 28 percent in 1910 to 80 percent in 2000. Suburbs, rather than central cities, accounted for most of the metropolitan growth. By 2000, half of the U.S. population lived in suburban areas.

The population of the West grew faster than the population in each of the other three regions of the country in every decade of the 20th century. The Northeast was the most densely populated region and had the highest percentage of its population living in metropolitan areas throughout the century.

Between 1900 and 2000, the mean center of population shifted 324 miles west and 101 miles south, moving from Bartholomew County, Indiana, to Phelps County, Missouri.

## Age and Sex Composition

At the beginning of the century, half of the U.S. population was less than 22.9 years old. At the century's end, half of the population was more than 35.3 years old, the country's highest median age ever.

Children under age 5 represented the largest 5-year age group in 1900 and again in 1950. During the last half of the century, the baby-boom generation's entry into an age group had a major impact on the growth of that age group. By 2000, the largest 5 -year age groups were ages 35 to 39 years and 40 to 44 years, a large segment of the baby-boom generation.

During the century, the population age 65 and over increased tenfold, from 3.1 million in 1900 to 35.0 million in 2000. The proportion of the population age 65 and over declined for the first time in the 1990s, due partly to the relatively low number of births in the late 1920s and early 1930s. Rapid growth of the
population age 65 and over will begin again in 2011, when the first of the baby-boom generation reaches age 65, and will continue for many years.

The United States' gender composition shifted from a majority male population to a majority female population around midcentury. The sex ratio (males per 100 females) declined every decade from 1910 to 1980, then increased in the 1980s and the 1990s. Among the regions, the West had the highest sex ratio and the Northeast had the lowest sex ratio for the entire century. Only seven states, all in the West, still had a larger male than female population at the end of the century.

## Race and Hispanic Origin

From 1900 to 2000, the number of non-Southern states with populations of at least 10 percent races other than White increased from 2 to 26 , reflecting the spread of diversity across the country.

In the Northeast, the Midwest, and the South, Blacks constituted the largest share of the population of races other than White in every decade of the 20th century, while in the West each of the races other than White represented the largest share during the century.

Only five states—Alabama, Arkansas, Mississippi, South Carolina, and West Virginia-had a lower percentage of races other than White in 2000 than in 1950.

From 1980 to 2000, the Hispanic population (of any race) more than doubled.

By the end of the century, three states-California, Hawaii, and New Mexico-and the District of Columbia had majority "Minority" populations (including Hispanics).

## Housing

Prior to 1950, over half of all occupied housing units were rented. By 1950, homeownership became more prevalent than renting. The homeownership rate continued to increase until 1980, decreased slightly in the 1980s, then increased in the 1990s, reaching the highest level of the century ( 66 percent) in 2000.

Each region's highest homeownership rate of the century was recorded in 2000. The Midwest had the highest homeownership rate for every decade of the century, except in 1910, when the West ranked first. The 1930s was the only decade when the proportion of owneroccupied housing units declined in every region. The largest increase in homeownership rates for each region occurred in the following decade, the 1940s, as the economy recovered from the Depression and experienced post-World War II prosperity.

Every region experienced an increase in vacancy rates during the 1950s, 1970s, and 1980s and a decrease in vacancy rates during the 1960s and the 1990s.

At the end of the 20th century, householders who were Black, Hispanic, or of two or more races were more likely to rent rather than own their homes.

## Households

In 1900, the most common household contained seven or more people; from 1940 to 2000, it contained two people.

In 1900, nearly half of the U.S. population lived in households of six or more people; by 2000, more than half lived in households of one, two, or three people.

Between 1950 and 2000, married-couple households declined from more than three-fourths of all households ( 78 percent) to just over one-half (52 percent). One-person households represented 1 of every 10 households ( 9.5 percent) in 1950, but constituted 1 of every 4 households (26 percent) by 2000.

During the period 1960 to 2000, women age 65 and over accounted for 27 percent to 33 percent of oneperson households, but just 5 percent to 8 percent of the total population.

In 1970, women represented about 1 of every 5 (21 percent) householders in the United States. By 2000, women composed more than 1 of every 3 (36 percent) U.S. householders.

In the last several decades of the century, male householders represented a greater share of one-person households. And male family householders with no wife present became increasingly likely to have children present in their households.

## INTRODUCTION

In 2002, the U.S. Census Bureau celebrates 100 years as an agency of the government of the United States. The first national population census was conducted in 1790, but it was not until March 6, 1902, that Congress passed legislation establishing a permanent Census Office in the Interior Department. The Census Office then officially opened its doors for business on July 1, 1902. One year later, the Census Office became the Bureau of the Census, as part of the newly formed Department of Commerce and Labor. The Census Bureau became part of the Department of Commerce in 1913, when the Department of Commerce and the Department of Labor were separated.

Since its inception, the U.S. Census Bureau has collected, tabulated, and published information on the popuIation of the United States. Over the last century, these efforts grew increasingly complex and their implementation increasingly sophisticated. The Census Bureau obtained information on a basic core of items from the entire population throughout the century, while evolving the methods and concepts used to collect data over the decades. This report consolidates information from each census, 1900 to 2000, to illustrate the remarkable changes in the American population in the 20th century.

The population trends in the United States reflect the country's trends in fertility and mortality and in internal and international migration. These components underlie the changes in the size of our population, its geographic distribution, its age and sex composition, and its racial and ethnic composition. They also influence changes in the country's housing and household composition. The trends examined in this report represent the subject areas covered by the population census of the United States on a 100-percent basis in Census 2000. That is, the data reflect information collected in census questionnaires for the entire population. Subject items collected on a sample basis (about one-sixth of all U.S. households since 1980) are not included.

This publication highlights the broad trends that have served to redraw America's demographic portrait continually over the course of the 20th century. As the

United States entered the 20th century, most of the population lived in the Northeast or the Midwest, in nonmetropolitan areas, was male, under 23 years old, White, and rented a home; nearly half lived in a household with five or more other people. One hundred years later, as the United States entered the 21 st century, most of the population lived in the South or the West, in metropolitan areas, was female, at least 35 years old, White (but much less so), owned a home, and lived alone or in a household with one or two other people.

These noteworthy population shifts often did not occur in a continuous or uniform fashion from census to census or for each geographic area. To examine the trends, this report covers the major decade-to-decade changes for each of the major subject areas of population size, growth, geographic distribution, age, sex, race and ethnic composition, housing, and households over the period 1900 to 2000 . The report focuses on overall trends for the country, regions, and states, with additional trends shown for metropolitan areas. The population trends are shown through the use of "headline-style" findings, maps, figures, and accompanying text. Appendix A provides detailed tables with more data for each decade of the century.

With minor exceptions, the data used to depict the demographic trends represent the population totals recorded at the time each census report was issued and do not reflect adjustments or corrections to the original data. While in-depth analytical studies of any of the individual subjects covered in this report could produce refined trends of the numbers themselves, such refinements would not alter the broad substantive findings. In terms of geographic coverage, most trends cover the conterminous 48 states and the District of Columbia for the period 1900 to 1950 and include data for Alaska and Hawaii beginning with 1960, the first census after they became states. State trends based on total population size include the 50 states and the District of Columbia for the entire century. For a detailed discussion of the sources and quality of the data used in this report for each subject area covered, see Appendix C.

## Chapter 1 <br> POPULATION SIZE AND GEOGRAPHIC DISTRIBUTION

## Chapter Highlights <br> POPULATION SIZE AND GEOGRAPHIC DISTRIBUTION

## National Trends

The United States population more than tripled from 76 million people in 1900 to 281 million people in 2000.

The United States ranked as the fourth most populous country in the world from the start of the century until the breakup of the Soviet Union in 1991, and as the world's third most populous country since then, after China and India.

The population growth of 32.7 million people in the 1990s was the largest numerical increase of any decade in U.S. history.
U.S. population density increased twofold during the period 1900 to 2000, but the level in 2000 (an average of 80 people per square mile) remained low in comparison with the density in most countries, and lower than the world population density of 120 people per square mile.

Between 1900 and 2000, the center of population shifted 324 miles west and 101 miles south, moving from Bartholomew County, Indiana, to Phelps County, Missouri.

The U.S. population grew increasingly metropolitan each decade, from 28 percent in 1910 to 80 percent in 2000.

The suburban portion of metropolitan areas, rather than central cities, accounted for most metropolitan growth during the century. By 2000, half of the U.S. population lived in suburban areas.

Nearly one-third of Americans lived in a metropolitan area with 5 million or more residents by the close of the century.

## Regional Trends

In 1900, the majority (62 percent) of the U.S. population lived in either the Northeast or the Midwest. However, by the end of the century, the majority ( 58 percent) of the population resided in either the South or West.

The population of the West grew faster than the population in each of the other three regions of the country in every decade of the 20th century.

The population density of the Northeast far exceeded the densities of the other regions from 1900 to 2000.

The Northeast also had the highest percentage of its population living in metropolitan areas for the entire 20th century.

## State Trends

In 1900, New York's population of 7.3 million exceeded that of any other state. In 2000, California had the largest population ( 33.9 million), and 10 other states (including New York) had populations larger than New York's population at the beginning of the century.

The 1990s was the first decade when none of the 50 states lost population, although the District of Columbia's population declined for the fifth consecutive decade.

From 1900 to 2000, Florida's ranking in population size increased more than any other state, from 33rd to 4th, followed by Arizona's, from 48th to 20th. Iowa's ranking declined the most, from 10th in 1900 to 30th in 2000.

Among the 50 states, Rhode Island had the highest population density from 1900 to 1960, and New Jersey had the highest population density from 1970 to 2000.

Alaska had the lowest population density of all states throughout the century. Excluding Alaska prior to its statehood in 1959, Nevada had the lowest population density every decade.

The percentage of population living in metropolitan areas increased for every state from 1910 to 2000. By 2000, the majority of the population in 37 of the 50 states lived in a metropolitan area.

## Chapter 1 <br> POPULATION SIZE AND GEOGRAPHIC DISTRIBUTION

The trends in the size and geographic distribution of the United States population reflect the country's historical trends in fertility, mortality, and internal and international migration. Over the course of the 20th century, the United States population experienced several major changes. Overall growth was substantial in both numerical and in percentage terms, although it varied from decade to decade. Although U.S. population growth was remarkable compared with other industrialized countries, the U.S. share of the world's population declined as less developed countries grew more rapidly. Population growth resulted in the country becoming increasingly more densely populated, but the large land area of the United States kept overall population density at a comparatively moderate level in global terms.

Regionally, the distribution of the U.S. population generally experienced a shift toward the South and the West. These regions dominated the 20th century's population growth, especially in the latter half of the century. The gains in total population share of the South and the West occurred at the expense of corresponding losses in population share of the Northeast and the Midwest.

State trends in population size, percentage growth, and rankings varied considerably. California accounted for one-sixth of national population growth during the 100-year period. Just eight states-California, Texas, New York, Florida, Illinois, Michigan, Ohio, and New Jersey-were responsible for more than half of the total population gain from 1900 to 2000. Not all states gained population in every decade. While several states in the South and the West stood out as clear
leaders in population growth trends during the century, states in the Northeast consistently ranked among the most densely populated.
"Metropolitanization" particularly characterized the demographic change of the United States in the 20th century. Prior to World War II, the majority of Americans lived outside of metropolitan territory. By the end of the century, 4 out of every 5 people in the United States resided in a metropolitan area. The growth of metropolitan areas in the 20th century was essentially a growth of the suburban population (defined here as the metropolitan population living outside of central cities), especially in the latter half of the century. In 2000, the central city population represented a smaller share of the U.S. population than it did in 1950. By the end of the century, the percentage metropolitan in the regions ranged from 74 percent in the Midwest to 90 percent in the Northeast. Eight states-California, Connecticut, Florida, Maryland, Massachusetts, New Jersey, New York, and Rhode Island-had all reached at least 90 percent metropolitan population by 2000.

The graphics and text in this chapter portray the decade-to-decade trends in the U.S. population. State trends often are covered graphically through the use of thematic maps showing data for the beginning, middle, and end of the century. Trends in population density and metropolitan population are also discussed. Detailed data for each decade for the United States, regions, and states on total population size, population density, and metropolitan classification are provided in Appendix Tables 1, 2, and 3. State trends and rankings based on total population size include Alaska and Hawaii.

## The U.S. population more than tripled from 76 million in 1900 to 281 million in 2000.

The United States population more than tripled, growing from 76 million people in 1900 to 281 million people in 2000 (see Figure 1-1). From the start of the century until the breakup of the Soviet Union in 1991, the United States ranked as the fourth most populous country in the world, and since 1991 as the world's third most populous country. The net addition of more than 200 million people to the U.S. population over the course of the 20th century represents more than the current population of every country in the world, except China, India, and Indonesia.

Net change in the U.S. population results from adding births, subtracting deaths, adding people who migrated to the United States, and subtracting people who left the country. During the past 100 years, net immigration to the United States was roughly 40 million people. In the same period, about 330 million babies were born, and nearly 165 million people died. The subtraction of total births minus total deaths yields a
natural increase of about 165 million people, which includes the natural increase contribution resulting from births and deaths to migrants.

Many social and demographic factors contributed to the huge growth of the U.S. population in the 20th century. Declining mortality was one such factor. As public sanitation, personal hygiene, and scientific and medical technology improved, life expectancy improved. Average life expectancy at birth increased by about 30 years over the course of the 20th century, from about 47 years in 1900 to about 77 years in 2000. Infants, in particular, benefited from 20th century advances in health and medicine. The infant mortality rate (the number of deaths to infants less than 1 year of age per 1,000 births) decreased sharply over the century, from a rate well in excess of 100 per 1,000 births at the start of the century, to a rate less than 10 per 1,000 births by the century's end.

Figure 1-1.
Total Population: 1900 to 2000
(Millions)

[^0]
## The 1990 to 2000 population increase was the largest in U.S. history.

Population growth in the United States varied greatly throughout the century, both numerically and in percentage terms. The population growth of 32.7 million in the 1990s was the largest numerical increase in U.S. history (see Figure 1-2).' The previous record increase was in the 1950s, a gain fueled primarily by the postWorld War II baby boom (1946 to 1964).

Population growth in the 1930s was the smallest of any decade during the period 1900 to 2000. The low growth in this Depression-era decade was due to low levels of fertility and negligible net international migration.

The decade-to-decade pattern of the percentage change in population followed the same up-and-down course as the numerical population change. However, while the maximum numerical population increase occurred in the last decade of the century, the highest percentage increase in the total U.S. population took place at the start of the century, 1900-1910. ${ }^{2}$ During

[^1]this period, the country experienced relatively high birth rates and, most significantly, the arrival of an exceptionally large number of immigrants. Immigration and high fertility levels also contributed to the high growth of the following two decades, 1910-1920 and 1920-1930.

The 1930s, which was the decade with the lowest numerical increase in population, also was the decade with the lowest percentage increase (7.2 percent). After this low point, the population growth rate increased in the 1940s and 1950s.

While the first period of rapid population growth was due primarily to immigration, the second period, from 1950 to 1960, was due primarily to the post World War II baby boom. The 1950s represented the second highest decade of population increase during the century in both numerical ( 28.6 million) and percentage (19.0 percent) terms.

After the high growth rate in the 1950s, the percentage increase in population declined over the next three decades. The U.S. population continued to grow, but at an increasingly slower rate. However, the rate of population growth increased during the 1990s for the first decade since the 1950s, exceeding the growth rate of the 1970s and 1980s, but still less than in the first three decades of the century.

Figure 1-2.
Population Increase by Decade: 1900 to 2000

Percent increase

# From 1950 to 2000, the United States and the rest of the developed world comprised a declining share of the world's population. 

Population estimates prepared by the U.S. Census Bureau for all countries of the world provide an opportunity to view the trend in U.S. population growth in a global context. ${ }^{3}$ As noted earlier, the United States ranked as the fourth most populous country in the world from 1900 until the breakup of the Soviet Union in 1991 and has ranked as the world's third most populous country since then. China and India ranked 1 st and 2 nd, respectively, in total population size throughout the 20th century.

In 1950, using present-day boundaries, the ten most populous countries were (in order): China, India, the United States, Russia, Japan, Indonesia, Germany, Brazil, the United Kingdom, and Italy. By 2000, the ten most populous countries were: China, India, the United States, Indonesia, Brazil, Russia, Pakistan, Bangladesh, Japan, and Nigeria.

Over the 50-year period, seven countries stayed among the ten most populous countries. The countries that

[^2]dropped out of the top ten (Germany, the United Kingdom, and Italy) were among the world's more developed countries (MDCs), and were replaced by Pakistan, Bangladesh, and Nigeria, all less developed countries (LDCs). ${ }^{4}$ Furthermore, Russia and Japan (both MDCs) dropped in rank, while the ranks of Indonesia and Brazil (both LDCs) increased.

China constituted about one-fifth of the world's population throughout the latter half of the century (see Figure 1-3). More than one-third of the world's population lived in either China or India. The U.S. share of the world's population declined each decade, from 6.0 percent in 1950 to 4.5 percent in 2000 . Due to faster growth rates of LDCs than of MDCs, the combined share of the United States and all other MDCs fell from about one-third (32 percent) of the world's population in 1950 to about one-fifth (19 percent) in 2000. In contrast, the share of world population increased in each of the less developed regions.

## U.S. population density tripled between 1900 and 2000, but remained relatively low compared to most countries.

Given a fixed land area, any increase or decrease in population is accompanied by a corresponding increase (or decrease) in population density. ${ }^{5}$ Over the course of the century, the population density of the United States tripled from 26 people per square mile of land area in 1900 to 80 people per square mile in 2000 (see Figure 1-4).

In 1959, Alaska and Hawaii became the 49th and 50th states, respectively. The addition of Alaska, the largest U.S. state in terms of land area, had a major impact on population density. In interpreting the historical trend, population density actually declined slightly from 1950 (not including Alaska and Hawaii prior to statehood) to 1960 (including Alaska and Hawaii). The effect of including Alaska and Hawaii on the trend in population density for the period 1900 to 1950 is shown in Figure 1-4.

Although population density tripled during the period 1900 to 2000, the U.S. density level in 2000 remained relatively low in comparison with most countries of the world, and lower than the overall world population density of 120 people per square mile.

Density levels vary considerably among the countries of the world. Among countries with 5 million or more people in 2000, Australia, Canada, and Libya each had population densities less than 10 people per square mile, while the Netherlands and South Korea had densities of over 1,200 people per square mile, and Bangladesh a density of nearly 2,500 . Of the world's ten most populous countries in 2000, Russia, Brazil, and the United States all had relatively low density levels (less than 100), followed by Indonesia, Nigeria, China, and Pakistan (in the 300 to 500 range), Japan and India (829 and 883, respectively), and then Bangladesh. ${ }^{6}$

## Between 1900 and 2000, the mean center of the U.S. population moved about 324 miles west and 101 miles south.

Each decade, after tabulating the results of the decennial census, the Census Bureau calculates the mean and median centers of population. The "mean center of population" refers to the point at which an imaginary, flat, weightless, and rigid map of the United States would balance perfectly if weights of identical value were placed on it so that each weight represented the location of one person on the date of the census.

Historically, the mean center of population has followed a trail that reflects the movement of the country's population across America. The trend follows a path indicating the settling of the frontier, waves of immigration, and internal migration west and south.

Over the course of the 20th century, the mean center of population continually moved westward, starting from Bartholomew County, Indiana, in 1900, progressing through Indiana, crossing Illinois, and by 2000 stopping in Phelps County, Missouri (see Figure 1-5). This represents a shift of 324 miles west and 101 miles south from its location at the start of the century.

From 1900 through 1940, the mean center of population was in the southern part of Indiana. From 1950 through 1970, it was in Illinois, and from 1980 through 2000, it was in Missouri.

During the second half of the century, the mean center continued to shift westward, and during the last five decades, began also to move in an increasingly southerly direction. Of the 101 miles the mean moved southward from 1900 to 2000, 22 miles were moved between 1900 and 1950, but 79 miles between 1950 and $2000 .^{7}$

[^6]Another measure of the geographic center of population is the "median center of population." The median center is located at the intersection of two median lines, a north-south line constructed so that half of the country's population lives east and half lives west of it, and an east-west line selected so that half of the country's population lives north and half lives south of it. The median center of population is less sensitive to population shifts than the mean center, since it is only affected by population movements that cross the north-south or the east-west median lines.

In every decade of the 20th century, the median center of population was located in either Indiana or Ohio. In 1900 and 1910, the median was in Randolph County, Indiana. At the next three censuses, 1920, 1930, and 1940, the median was located farther east in Darke County, Ohio, a southwestern county in Ohio bordering Indiana. The eastward trend of the median in 1920, 1930, and 1940 compared with 1900 and 1910 may be attributed in part to the impact of migration to industrial urban areas in the Northeast.

The relatively strong westward and southerly shift of the mean center of population in the latter half of the 20th century is paralleled by movement of the median center during the same period. In 1950, the median center had returned to Indiana in a county (Wayne county) adjacent to and south of its location in 1900 and 1910 (Randolph county). Over the next five decades, the median center moved much farther south and west within the state of Indiana, reaching Daviess County at the close of the century. The largest shifts in the median center of population occurred during the 1970 s and 1980s.

# The South and West accounted for nearly two-thirds of the U.S. population increase from 1900 to 2000. 

While all four regions ${ }^{8}$ of the United States grew considerably in the 20th century, the South and the West experienced the largest increases in population, 76 million and 59 million, respectively. Combined, these two regions increased by 471 percent during the century, compared with the combined increase of 149 percent for the Northeast and Midwest. Between 1900 and 2000, the combined increase of 135 million people in the South and the West represented 66 percent of the U.S. population increase of 205 million people.

From 1900 to 2000, the population more than doubled in the Northeast ( 21 million to 54 million) and in the Midwest ( 26 million to 64 million). The South's population during this period quadrupled from 25 million to 100 million, while the West's population was more than fifteen times larger in 2000, increasing from 4 million in 1900 to 63 million at the end of the century (see Figure 1-6).

From 1900 to 1930, the Midwest was the most populous region of the country. From 1940 onward, the South had the largest population of all the regions. By 2000, the West's population (63 million) had nearly reached the Midwest's population (64 million). The Northeast (by far the smallest in land area) became the country's least populous region by 1990 and remained the least populous in 2000.

Despite the West's phenomenal growth in population, it remained the region with the smallest proportion of the U.S. population as recently as 1980 (see Figure 1-7). As recently as 1950, the West's proportion (13 percent) of the total U.S. population was just half of the next largest region (Northeast, 26 percent). Yet by 1990, the West's population had become a larger proportion of the total

[^7]U.S. population than the Northeast's, and appears likely to overtake the Midwest as the country's second most populous region in the near future.

One of the most significant demographic trends of the 20th century has been the steady shifting of the population west and south. (See the earlier discussion of the mean and median centers of population, Figure 1-5.) In 1900, the majority (62 percent) of the population lived in either the Northeast or the Midwest. This combined proportion declined each decade during the century. By 1980, the majority ( 52 percent) of the country's population resided in either the South or the West. This trend continued to the end of the century, with the combined South and West regional populations representing 58 percent of the total population of the United States in 2000.

More than one-third of the U.S. population lived in the South in 2000, and about one-third (between 31 to 36 percent) lived in this region over the entire century. The Northeast represented about one-fourth of the U.S. population for most of the century (ranging between 24 percent to 28 percent during the period 1900 to 1970), but its share declined every decade since 1910 , to about one-fifth of the U.S. population in 2000. The Midwest's share of the country's total population declined every decade throughout the century, and its percentage-point decline was even more than the Northeast's. The Midwest's share fell by 12 percentage points, from more than one-third (35 percent) of the total population in 1900 to just under one-fourth (23 percent) in 2000. The West represented just 5 percent of the country's population in 1900, but its share increased every decade of the century and reached 22 percent in 2000. As a result of the changing regional distribution of population over the course of the century, the West, Midwest, and Northeast each represented similar fractions (around one-fifth) of the total U.S. population in 2000.

Figure 1-7.
Population Distribution by Region: 1900 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## The West grew faster every decade than all other U.S. regions.

The population of the West grew faster than the other three regions of the country in every decade of the 20th century (see Figure 1-8). In fact, with the exception of the 1930s, the rate of growth in the West was at least double the rate of the other regions for the decades from 1900 to 1960.

For most of the century, the West and the South experienced relatively higher growth rates than the Northeast and the Midwest. The Northeast and the Midwest both had relatively lower growth rates in the 1930s and each decade from the 1960s through the 1990s. The Northeast also had a growth rate below 10 percent in the 1940s. Every region had growth rates above 10 percent during the century's first three decades, when net immigration and fertility rates were generally higher, and again in the 1950s during the peak baby boom years.

In the first third of the century (i.e., 1900 to 1930), the Northeast had the second highest growth rate among the regions. The South replaced the Northeast as the second fastest growing region in the country in the 1930s and remained so for the rest of the century.

The Northeast and Midwest experienced similar growth rate trends every decade since the 1910 to 1920 period. Either the Northeast or the Midwest was the slow-est-growing region during every decade of the century, with the exception of 1910 to 1920, when the South had a slightly lower growth rate than the other regions.

The growth of the population peaked in the decade 1900 to 1910 for both the Northeast ( 23 percent) and the West (67 percent). The 1950s represented the peak decade for the growth of the population in the Midwest (16 percent), and the 1970s was the fastestgrowing decade in the South ( 20 percent).

The growth of the population reached its lowest point for both the South ( 10 percent) and the West ( 17 percent) in the 1930s Depression-era decade, which was the period with the lowest growth rate for the United States as a whole. The West's lowest percentage growth during the century (in the 1930s) exceeded the Midwest's highest percentage growth (in the 1950s). The lowest growth decade for the Northeast was the 1970s, with an increase of just 0.2 percent, and the Midwest's lowest growth decade was the 1980s ( 1.4 percent).

Figure 1-8.
Percent Change in Population per Decade by Region:
1900 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## The Northeast was the most densely populated region throughout the 20th century.

While the Midwest (until 1930) and the South (since 1940) had the largest populations among the regions, and the West grew the fastest each decade, the population density of the Northeast far exceeded the densities of the other regions from 1900 to 2000 (see Figure 1-9). The West's land area, which constitutes nearly half of the total U.S. land area, had the fewest people per square mile of the regions.

The Midwest and the South had similar density levels and trends over the period 1900 to 1970, with the Midwest's density slightly higher than the South's. Since 1980, the South's density level has exceeded the Midwest's level, making the South the second most densely populated region, and the gap between these two regions widened between 1980 and 2000.

Population density levels reflect a combination of population and land area. Although the Northeast represented the smallest share (19 percent) of the U.S. population in 2000, it represented an even smaller share (about 5 percent) of the U.S. land area. Thus, the Northeast had about one-fifth of the U.S. population living in just one-twentieth of the country's land area.

In contrast, while the West also represented about onefifth (22 percent) of the U.S population in 2000 , this population lived in 50 percent of the U.S. land area, resulting in low population density. In 2000, the Midwest's shares of population and land area were similar, 23 and 21 percent, respectively, while the South's population share ( 36 percent) was greater than its share ( 25 percent) of the U.S. land area.

Density levels, along with total population, increased every decade for each region of the country, except for the West, where a slight decline occurred from 1950 to 1960, due to the addition to the region of Alaska, a large-area, low-density state (see Appendix Table 2). Even after 100 years of population growth and high rates of growth in the West and, in recent decades, the South, density levels in the Midwest, South, and West in 2000 were still less than the Northeast's population density at the start of the century. Between 1900 and 2000, the average number of people per square mile increased from 130 to 330 in the Northeast, from 35 to 86 in the Midwest, from 28 to 115 in the South, and from 3 to 36 in the West.

Figure 1-9.
Population Density by Region: 1900 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## In 1900, nearly half of the states had fewer than 1 million people. By 2000, only 7 states (and the District of Columbia) had a population under 1 million.

At the beginning of the century, no state had 10 million or more people. In 1900, state population totals ranged from a low of 42,000 in Nevada to 7.3 million in New York (see Appendix Table 1). By 1950, three states, New York, Pennsylvania, and California had passed the 10million mark. At the end of the century, 7 states had reached a population of at least 10 million-California, Texas, New York, Florida, Illinois, Pennsylvania, and Ohio. The state with the most people in 2000 was California, with a population of 33.9 million.

In 1900, New York and Pennsylvania were the only states with populations of at least 5 million (see Figure 1-10). By 1950, four states-Illinois, Michigan, Ohio, and Texas had between 5 and 10 million people. (As noted above, after the first five decades of the century, New York and Pennsylvania had crossed the threshold of 10 million.) By 2000, a total of 13 states had a population size between 5 and 10 million, comprised of 12 new states, plus 1 holdover, Michigan, from 1950.

Twenty-three states had fewer than 1 million residents in 1900, and 12 of these states were in the West. ${ }^{9}$ By 1950, the number of states with fewer than 1 million residents had fallen to 16 , and 9 of these were western states. Only 7 states had populations of less than 1 million throughout the century. In 2000, Wyoming had the fewest people, with a population of 494,000, followed by Vermont, Alaska, North Dakota, South Dakota, Delaware, and Montana. ${ }^{10}$

[^8]Florida was the only state to grow from a population of less than 1 million at the start of the century to a population of over 10 million by the century's end.

Only 4 states-California, Illinois, Ohio, and Texasgrew from between 1 and 5 million in 1900 to join the 10-million-and-over club by the end of the century. California had already grown to a population of over 10 million by midcentury, increasing greatly from just 1.5 million people in 1900 to 10.6 million people in 1950. Illinois reached 10 million by 1960 and Ohio and Texas by 1970.

Arizona and Washington were the only states to increase from less than 1 million population in 1900 to between 5 million and 10 million ( 5.1 and 5.9 million, respectively) in 2000.

In 2000, California was the only state with a population of more than 30 million. Texas (with a population of 20.9 million in 2000 ) was the only other state to have crossed the 20 -million threshold.

As mentioned above, New York's total population of 7.3 million in 1900 was greater than any other state. By 2000, the populations of 11 states exceeded this figure: in addition to the 7 states with 10 million or more population listed above, Michigan ( 9.9 million), Georgia ( 8.2 million), New Jersey ( 8.4 million), and North Carolina ( 8.0 million) had populations that were larger than New York's had been at the start of the 20th century.

# California, Texas, Florida, and New York accounted for more than one-third ( 38 percent) of the U.S. population increase in the 20th century. 

The U.S. population increased by more than 200 million people between 1900 and 2000. The population increases in the 4 most populous states at the end of the cen-tury-California ( 32.4 million), Texas ( 17.8 million), Florida ( 15.5 million), and New York ( 11.7 million)together represented 38 percent of the total growth in the United States over the past 100 years. These were also the only states that increased by more than 10 million people over this period (see Figure 1-11).

California's increase alone accounted for nearly onesixth of the total U.S. increase and was more than the combined increase of 27 states. In 1900, California's population was about the same as the population of Kansas ( 1.5 million) but, over the next 10 decades, California increased by 32.4 million while Kansas grew by an additional 1.2 million people.

Over one-half of the U.S. population increase in the 20th century occurred in just eight states. They included

Illinois, Michigan, Ohio, and New Jersey, in addition to California, Texas, New York, and Florida. The population increase in ten additional states represented another 25 percent of the total U.S. increase. Thus, over three-fourths of the population increase in the United States from 1900 to 2000 took place in just 18 states.

The population of 10 states increased between 5 million and 10 million during the period from 1900 to 2000. With the exception of Arizona, all of these states are "coastal" states, meaning states bordering either the Atlantic or Pacific Oceans, the Gulf of Mexico, or the Great Lakes.

Thirteen states (and the District of Columbia) gained fewer than 1 million people during the 20th century. Several of these states are geographically contiguous, such as Maine, New Hampshire, and Vermont in New England, and the northern interior states of Montana, Wyoming, North Dakota, South Dakota, Nebraska, and lowa.

Source: U.S. Census Bureau, decennial census of population, 1900 and 2000.

# The population declined in more states in the 1930s than during any other 20th century decade, and the 1990s was the first decade when no state's population declined. 

Although every state's population was larger at the century's end than at the start, the population of every state did not grow in each individual decade. During the century, a decline in population from one census to the next in either a state or the District of Columbia occurred 32 times (see Table 1-1).

The 32 instances of population decline during the ten decades of the century took place in just 15 states (and the District of Columbia). The District of Columbia's population declined most often during the period, losing population every decade since the 1950s. North Dakota's population fell four times between censuses; Mississippi's and West Virginia's populations fell three times; and Arkansas's, lowa's, Oklahoma's, South Dakota's, and Vermont's populations each fell twice. Seven states experienced one decade of population decline during the century: Alaska, Kansas, Montana, Nebraska, New York, Nevada, and Wyoming. By region, the group represents five states in the Midwest, four (and the District of Columbia) in the South, four in the West, and two in the Northeast.

Of the 32 instances of population decline, southern states (and the District of Columbia) accounted for 15 , midwestern states for 10, western states for 4, and northeastern states for 3 declines.

More states declined in population in the 1930s than in any other decade of the 20th century. Nearly all the state population declines in this period occurred in Great Plains states, extending northward from Oklahoma to Kansas, Nebraska, South Dakota, and North Dakota.

Only states in the South and Midwest lost population between censuses during the period 1940 to 1970. In the 1950s, only southern states lost population. The only states outside the South and the Midwest to lose population since 1930 were New York (1970s), Vermont (1930s), and Wyoming (1980s). New York's population decline $(679,000)$ was by far the largest of any decade: no other state level decline exceeded 200,000.

The 1990s was the first decade when none of the 50 states lost population, although the District of Columbia's population declined for the fifth consecutive decade.

Table 1-1.
States Experiencing Intercensal Population Decline: 1900-1910 to 1990-2000

[^9]Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

# Nine western states and Florida accounted for the ten fastest-growing states from 1900 to 1950 and eight western states plus Florida and Texas were the fastest growing from 1950 to 2000. 

At the state level, patterns of percentage change in population portray a different picture than patterns of numerical population change. In any period, a state with a small base population may not grow a large amount in terms of population numbers, but may increase by a large proportion of its original population size.

From 1900 to 2000, Nevada's population grew faster (4,620 percent) than the population of any other state. Arizona ranked second, with an increase of 4,074 percent. Western states accounted for 9 of the 10 fastest-growing states during this period. The southern state of Florida ranked third, with an increase of 2,924 percent.

In contrast, no western state ranked among the ten slowest-growing states during the century, while states in each of the other regions did. Iowa had the lowest percentage increase ( 31 percent) from 1900 to 2000, followed by Nebraska (60 percent).

During the first half of the century, states in the West also accounted for 9 of the 10 states with the highest percentage growth in population (see Figure 1-12). The top five states from 1900 to 1950 were (in rank order): California, Arizona, Florida, Washington, and Nevada. During this period, California grew by more than 600 percent. The populations of the ten fastestgrowing states at least tripled (increased by 200 percent or more). The populations of an additional 12 states (and the District of Columbia) more than doubled in size.

From 1900 to 1950, the ten slowest-growing states all grew by less than 50 percent. Vermont grew the slowest (10 percent), followed by lowa, Nebraska, Missouri, and New Hampshire.

Western states also accounted for 8 of the 10 fastestgrowing states in the 1950 to 2000 period. From 1950 to 2000, the five fastest-growing states (in rank order) were: Nevada, Arizona, Florida, Alaska, and Colorado. Nevada's population increased by more than 1,100 percent during this period.

During the second half of the century, the populations of 7 states at least tripled, while the populations of 11 additional states more than doubled.

From 1950 to 2000, the ten states or state equivalent with the lowest percentage changes were: the District of Columbia, West Virginia, North Dakota, lowa, South Dakota, Pennsylvania, New York, Nebraska, Mississippi, and Rhode Island. During this period, the populations of the District of Columbia and West Virginia declined by 29 percent and 10 percent, respectively.

Comparing population change in the first and second halves of the century, California grew fastest in the first part and Nevada in the second half. Nevada, Arizona, and Florida ranked among the five fastestgrowing states in both periods. In addition, California, New Mexico, and Washington ranked among the ten fastest-growing states for each 50-year period.
lowa was the only state to appear among the five slowest-growing states in population for both halves of the century, while Nebraska and Mississippi were among the ten slowest-growing states.

The population of 11 western states, Florida, and Texas at least doubled in size during both 50-year periods.

Figure 1-12.

Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

## Florida's rank by population size jumped the most, while Iowa's fell the most from 1900 to 2000.

The numeric and percentage change in population size for the 50 states and the District of Columbia varied widely over the century. These differences produced marked shifts in the relative ranking of states in terms of population size (see Table 1-2).

Between 1900 and 2000, 15 states ranked among the 10 most populous at least once. Six of them were among the ten largest throughout the centuryIllinois, Michigan, New York, Ohio, Pennsylvania, and Texas. Of the remaining nine, four were among the ten largest in 1900 but then dropped below this rank and never re-entered-Indiana, lowa, Missouri, and Massachusetts; three entered the ten largest and never left-California, Florida, and New Jersey; North Carolina was the tenth largest in 1950; and Georgia was the tenth largest state in 1910 and in 2000 (see Appendix Table 1).

New York had the largest state population from 1900 through the 1960 census. California became the largest state by the 1970 census and has remained the most populous. Texas became the second largest state by 2000, dropping New York to third.

State rankings fluctuate from census to census depending on population growth. However, some state rankings progressively increased during the century, while others progressively declined. In 2000,

15 states were ranked at their highest level of the century. All of these states were either in the West (ten states or the South (five states). In contrast, 11 states ranked at their highest point during the century in 1900. Most of these are in the Northeast (Maine, New Hampshire, Rhode Island, and Vermont) and the Midwest (Indiana, lowa, Missouri, and Nebraska). None of these states is in the West. Although five states in the South were at their peak rank in 2000 (Delaware, Florida, Georgia, Texas, and Virginia), three states in the South had their highest population rank in 1900—Kentucky, Mississippi, and Tennessee.

While population changes altered the state ranking order, most state ranks did not vary by more than ten positions during the 100-year period. Five states increased their ranking by more than ten places: four states in the West (Arizona, California, Nevada, and Washington), plus Florida, which increased in rank more than any other state, from 33rd to 4th. (Arizona's rank increased nearly as much, from 48th in 1900 to 20th in 2000.)

Seven states and the District of Columbia dropped by more than ten places in their ranking over the century, all of them either in the Midwest or the South. lowa's ranking declined the most, from 10th in 1900 to 30th in 2000.

Table 1-2.
States Ranked by Population Size: 1900, 1950, and 2000

Note: States in color are or have ranked in the top ten most populous states.
Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

## Among the 50 states, New Jersey, Rhode Island, Massachusetts, and Connecticut had the highest population densities throughout the century.

Since population density is determined both by population size and by land area, relatively less-populated states can have a high population density, and relatively more-populated states can have a low population density. For example, Rhode Island ranked first among the 50 states in population density in each census from 1900 through 1960, even though it ranked among the smaller states in population size. ${ }^{11}$ Conversely, Texas, which became the second-most populated state in 2000, still ranked 28th in terms of population density at the end of the century.

At the beginning of the century, all the more densely populated states were in the eastern half of the country (see Figure 1-13). State densities generally increased over time as the population increased, since the changes in the land area of states during the period were minimal. ${ }^{12}$ Even in 2000, the eastern half of the country remained more densely populated than the western half.

Most of the states with a high population density have a relatively small total land area. As noted above, Rhode Island had the highest population density among the 50 states from 1900 to 1960. By 1970, New Jersey had become the country's most densely populated state and has remained so since then. At the end of the century, both of these states had

[^10]population densities of more than 1,000 people per square mile (see Appendix Table 2). Massachusetts had the second or third highest density level throughout the century, and Connecticut ranked fourth every decade from 1900 to 2000.

Throughout the 20th century, all of the least densely populated states were relatively large-area states in the West and Midwest regions. Maine was the Northeast region's least densely populated state throughout the century. From 1900 to 1950, the least densely populated state in the South was either Florida or Texas. From 1960 to 2000, Oklahoma and Arkansas had the lowest population densities in the South. For the West region and for the United States, Alaska (with just over one person per square mile in 2000) had the lowest population density of all the states, a result of the combination of a relatively small population size and a very large land area. Prior to Alaska's statehood in 1960, the state with the lowest population density every decade was Nevada.

The number of states with more than 200 people per square mile increased from 3 (New Jersey, Rhode Island, and Massachusetts) in 1900 to 12 in 2000. The nine additional states, ranked by density in 2000, are: Connecticut, Maryland, New York, Delaware, Florida, Ohio, Pennsylvania, Illinois, and California.

In 1900, 14 states (and Alaska) had densities of fewer than 10 people per square mile. They included Florida and California, which, as noted above, had increased to more than 200 people per square mile by the end of the century. Five states-South Dakota, North Dakota, Montana, Wyoming, and Alaska-still had fewer than ten people per square mile in 2000.

Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

## In 1950, the U.S. population became predominantly metropolitan and became increasingly more metropolitan in each subsequent decade.

The U.S. Census Bureau defined metropolitan population concentrations ${ }^{13}$ for the first time in 1910. At that time, 26.1 million people lived in 19 metropolitan districts of 200,000 or more population and cities of 100,000 to 200,000 and their adjacent territory, leaving 65.9 million who lived in nonmetropolitan territory. With each passing decade, the metropolitan population increased, while the nonmetropolitan population generally decreased (see Figure 1-14).

While metropolitan concentrations certainly grew as a result of births and migration, they also grew as a result of territorial expansion. Over the course of the century, the changing definition of "metropolitan" caused new areas to achieve metropolitan status and existing metropolitan areas to acquire more territory.

[^11]During the early part of the century, the metropolitan population grew quickly, due in part to the influx of immigrants into large cities, while the nonmetropolitan population changed very little. The smallest increase in the metropolitan population occurred during the 1930s ( 8.2 million people). This was also the last decade when the nonmetropolitan population increased, although it remained larger than the metropolitan population into the 1940s.

By 1950, the U.S. population had become predominantly metropolitan for the first time, and the metropolitan population exceeded the nonmetropolitan population by 18.3 million people. By 2000, the metropolitan population ( 226 million) was four times the size of the nonmetropolitan population ( 55 million).

From 1910 to 2000, the metropolitan population grew by nearly 200 million people, with the largest increase, 33.3 million, occurring from 1990 to 2000.

Figure 1-14.
Total Population by Metropolitan Status: 1910 to 2000
(Millions)

# While the metropolitan population grew rapidly during the century, most of that growth occurred in the suburbs, with little change in the percentage of population living in central cities. 

Metropolitan areas accounted for a growing proportion of the U.S. population over the course of the century. In 1910, less than a third (28 percent) of the total population lived in metropolitan areas, but by 1950, more than half of the U.S. population lived in metropolitan areas. In 2000, the metropolitan population represented 80 percent of the U.S. resident total of 281.4 million people (see Figure 1-15).

The highest percentage increase in metropolitan population growth occurred from 1920 to 1930, when metropolitan areas grew by 52 percent. The lowest metropolitan percentage growth occurred from 1980 to 1990, when metropolitan areas grew by 14 percent.

Metropolitan areas include two parts: central cities and suburbs. ${ }^{14}$ From 1910 to 2000, suburbs accounted for most of the growth of metropolitan areas.

[^12]From 1910 to 1960, the population of central cities accounted for a larger proportion of the total population than the population living in suburbs. For example, in 1910, 21 percent of the total U.S. population lived in central cities, while only 7 percent of the population lived in suburbs.

From 1910 to 1930, both central cities and suburbs grew rapidly. Growth in the 1930s continued, but at a slower pace. From 1940 onward, suburbs accounted for more population growth than central cities and, by 1960, the proportion of the total U.S. population living in the suburbs (31 percent) was almost equal to the proportion of the population living in the central cities (32 percent).

From 1940 to 2000, the proportion of the population living in central cities remained relatively stable, while the suburbs continued to grow substantially. By 2000, half of the entire U.S. population lived in the suburbs of metropolitan areas.

Figure 1-15.
Percent of Total Population Living in Metropolitan Areas and in Their Central Cities and Suburbs: 1910 to 2000

Source: U.S. Census Bureau, decennial census of population, 1910 to 2000.

## Since 1990, more than half of the U.S. population has lived in metropolitan areas of at least 1 million people.

Most of the metropolitan population lives in relatively large concentrations (see Figure 1-16). In 1950, only 14 metropolitan areas had populations of at least 1 million people, which constituted less than a third (29 percent) of the total U.S. population. By 2000, 50 metropolitan areas had populations of at least 1 million people, which accounted for over half ( 57 percent) of the total U.S. population. ${ }^{15}$

From 1950 to 2000, the population living in metropolitan areas of at least 1 million people increased by 117.1 million and accounted for 83 percent of the total metropolitan growth and 90 percent of the total U.S. population growth. It is important to note that the growth of the different size categories of metropolitan areas is directly affected by the addition of new metropolitan

[^13]areas, the movement of existing metropolitan areas into larger size categories due to population increase, and the territorial growth of metropolitan areas due to changing metropolitan boundaries, which often adds counties to existing metropolitan areas.

Between 1950 and 2000, the share of the population living in metropolitan areas with 1 million up to 5 million people and with 5 million or more people increased greatly (by 10.2 and 17.7 percentage points, respectively), while the share of the population living in the other two size categories stayed within a narrow range. Although the share of the population living in metropolitan areas of 250,000 up to 1 million, and less than 250,000 increased in two decades during the 50 -year period, a smaller share of the U.S. population lived in these areas in 2000 than in 1950. For the two larger size classes, the lowest population share occurred in 1950, while for the two smaller size classes, the lowest population share occurred in 2000.

Figure 1-16.
Percent of Total Population Living in Metropolitan Areas by Size of Metropolitan Area Population: 1950 to 2000

[^14]
## From 1950 to 2000, New York was the most populous metropolitan area.

Since 1950, the ten largest metropolitan areas have always had populations of 1 million or more. In 1950, Cleveland, Ohio, the 10th largest metropolitan area had nearly 1.5 million people. By 2000, the 10th largest metropolitan area, Houston-GalvestonBrazoria, Texas, had a population of 4.7 million (see Table 1-3).

In 1950, New York and Chicago were the only metropolitan areas with populations of 5 million or more. Their combined population in 1950 ( 18.4 million) accounted for 12.2 percent of the total U.S. population. ${ }^{16}$ By 2000, they had been joined by 7 other metropolitan areas, ${ }^{17}$ creating a combined population of 84.1 million, or 29.9 percent of the U.S. total. By 2000, nearly 1 in 3 Americans lived in a metropolitan area with 5 million or more residents.

While metropolitan areas grew significantly from 1950 to 2000 , some relatively slower-growing metropolitan areas in the Northeast and the Midwest dropped out of the category of the ten largest metropolitan areas. For example, the tenth largest metropolitan area in 1950, Cleveland, Ohio, was no longer in the top ten by 1960.

[^15]St. Louis, Missouri, and Pittsburgh, Pennsylvania, dropped out of the top ten by 1980, when HoustonGalveston, Texas, and Dallas-Fort Worth, Texas, were added for the first time.

From 1950 to 2000, New York was the largest metropolitan area in the United States, with a population ranging from 12.9 million people in 1950 to 21.2 million people in 2000. ${ }^{18}$ In 2000, New York accounted for 7.5 percent of the total U.S. population. From 1950 to 1970, Chicago and Los Angeles were the second and third largest metropolitan areas in the United States, respectively. However, from 1980 to 2000, they switched ranks and Los Angeles was the second most populous metropolitan area.

While New York remained by far the largest metropolitan area in the United States from 1950 to 2000, its proportional lead over the second largest metropolitan area slowly closed from 1950 to 1990 and then slightly increased from 1990 to 2000. In 1950, New York was more than twice the size of Chicago, the second largest metropolitan area. However, by 2000, New York was about 1.3 times the size of Los Angeles, the next largest metropolitan area.

[^16]Table 1-3.
Ten Most Populous Metropolitan Areas: 1950 to 2000

[^17]Source: U.S. Census Bureau, decennial census of population, 1950 to 2000.

## The density of central cities declined during the second half of the century, yet remained far higher than the densities of suburban areas, which increased, and the densities of nonmetropolitan areas, which were steady during the period.

Metropolitan population density levels remained higher than nonmetropolitan density (see Figure 1-17) since 1950, when metropolitan areas were first defined. From 1950 to 2000, the density of metropolitan areas ranged from 299 to 407 people per square mile, and the density of nonmetropolitan territory ranged from 19 to 24 people per square mile.

While the density of nonmetropolitan areas remained relatively stable from 1950 to 2000 , the density of metropolitan areas fluctuated. ${ }^{19}$ The peak of metropolitan population density in the last half of the century occurred in 1950. Then, it declined steadily from 1950 to 1980, driven primarily by the steep decline in the population of central cities, one of the components of metropolitan areas. As Figure 1-17 shows, the density of central cities was substantially higher than the density of suburban and nonmetropolitan areas throughout the second half of the century, although it declined every decade during this period, from a peak of 7,517 people per square mile in 1950 to a low of 2,716 people per square mile in 2000.

[^18]The decline of central city populations was partly offset by the movement of population into the suburbs, the other component of metropolitan areas. The density of suburban areas steadily increased from 1950 to 1970, however, this increase had little effect on the overall density of metropolitan areas. To some extent, this phenomenon reflects the addition of land area (usually relatively lower density suburban counties) to metropolitan areas as a whole with each passing census. ${ }^{20}$ Increased land area, coupled with population declines of many central cities, resulted in an overall decline in metropolitan density between 1950 and 2000.

In the 1980s, metropolitan area density increased slightly, then decreased slightly in the 1990s. Similarly, the density of the suburban areas increased slightly from 1980 to 1990, then leveled off from 1990 to 2000. Although the density of central cities continued to decline in both the 1980s and 1990s, the rate of the decline slowed considerably during this period.

[^19]Figure 1-17.
Population Density by Metropolitan Area Status: 1950 to 2000

Source: U.S. Census Bureau, decennial census of population, 1950 to 2000.

# The Northeast had the highest percentage of people living in metropolitan areas of all four regions for the entire century. 

The percentage of people living in metropolitan areas increased in every decade for every region. In 1910, more than half of the Northeast's population, about a quarter of the Midwest's and the West's, and about a tenth of the South's population was metropolitan. By 2000, at least three quarters of the populations in the Northeast, the South, and the West were metropolitan and nearly three quarters ( 73.8 percent) of the population in the Midwest lived in metropolitan areas (see Figure 1-18).

The proportions of the populations that lived in metropolitan areas grew relatively faster in the South and the West than in the Northeast and the Midwest. In the South, the metropolitan population increased from 9 percent in 1910 to 75 percent in 2000, and in the West it grew from 28 percent in 1910 to 87 percent in 2000.

The ranking of the regions in terms of percentage metropolitan remained fairly stable over the century. The Northeast had the highest percentage of people living in metropolitan areas for the entire century. From 1910 to 1990, the Northeast was followed by the

West, the Midwest, and then the South. However, the South passed the Midwest for the first time in 2000, making the Midwest the least metropolitan of the regions.

Comparing the regions to the national average in terms of percentage of metropolitan population, the Northeast remained above the national average throughout the century and the West stayed above the national average from 1930 to 2000. However, the percentage metropolitan in the South and Midwest remained below the national average for the whole century.

As all four regions increased their metropolitan populations, the difference in the proportion living in metropolitan areas between the regions converged. The largest differential (54 percentage points) between the regions in the percentage metropolitan was in 1930 (74 percent in the Northeast compared with 20 percent in the South). By 2000, the difference between the regions had narrowed to 16 percentage points ( 90 percent in the Northeast compared with 74 percent in the Midwest).

Figure 1-18.

## Percent of Population Living in Metropolitan Areas by Region: 1910 to 2000

Source: U.S. Census Bureau, decennial census of population, 1910 to 2000.

# In 1910, no state had 75 percent or more of its population living in metropolitan areas. In 2000, more than one-third of the states had 75 percent or more of their populations living in metropolitan areas. 

The percentage of population living in metropolitan areas increased for every state from 1910 to 2000. In 1910, only five states (Maryland, Massachusetts, New Jersey, New York, and Rhode Island), concentrated primarily along the northeastern seaboard, had a majority of their populations living in metropolitan areas and no state had 75 percent or more of its population living in metropolitan areas. ${ }^{21}$ Thirty-three states had less than a quarter of their populations living in metropolitan areas, of which 19 states had no metropolitan population.

By 1950, the number of states with a majority metropolitan population had tripled to 15 , and these states were more dispersed throughout the country, spreading into parts of the Midwest and West. By 2000, at least 50 percent of the population in 37 states lived in metropolitan areas, and no states had less than 25 percent metropolitan. As Figure 1-19 shows, by 2000, more than one-third (21) of the states had 75 percent or more of their populations living in metropolitan areas and they were distributed among every region. Some clustering of these states occurred along the Atlantic coast from Massachusetts to

[^20]Virginia and into the large midwestern states (Ohio, Michigan, and Illinois). Still another cluster extended inland from California including Nevada, Utah, Arizona, and Colorado.

While increasing numbers of states were becoming mostly metropolitan, as late as 1970, three states (Alaska, Vermont, and Wyoming) had no metropolitan population at all. By 1980, all 50 states had a portion of their populations living in metropolitan areas.

The top ten states with the highest percentage metropolitan remained fairly stable from 1910 to 2000. Seven states (California, Connecticut, Maryland, Massachusetts, New Jersey, New York, and Rhode Island) were consistently among the top ten. By 2000, all seven of these states, plus Florida, were at least 90 percent metropolitan. Illinois and Pennsylvania were also among the states with the highest proportions of metropolitan population for large portions of the century (1910 to 1970 for Illinois, and 1910, 1930 to 1960, and 1990 for Pennsylvania).

On the other hand, five states (Idaho, North Dakota, South Dakota, Vermont, and Wyoming) remained among the ten states with the lowest percentage metropolitan and, by 2000, none of these states had a majority metropolitan population. Three more states, Maine, Mississippi, and Montana, each ranked among the ten states with the lowest percentage metropolitan for all but one census during the period 1910 to 2000.

Figure 1-19.

## Percent of Population Living in Metropolitan Areas

 by State: 1910, 1950, and 2000

Percent of population in metropolitan areas

Source: U.S. Census Bureau, decennial census of population, 1910, 1950, and 2000.

# The percentage of the U.S. population living in the ten largest cities increased to a peak in 1930, then declined every following decade of the century. 

Despite the significant growth of metropolitan areas in the United States, the percentage of the population living in the ten largest cities grew steadily in the first three decades of the 20th century, but declined appreciably over the next seven decades. The percentage of the population living in the ten largest cities peaked in 1930 (15.5 percent) and fell every decade thereafter, reaching its lowest point in 2000 ( 8.5 percent, see Figure 1-20).

The growth of the ten largest cities from 1900 to 1930 and their subsequent decline as a proportion of the U.S. population mirrors the growth and decline of the total central city population in the United States in the 20th century. During the first part of the century, immigrants as well as natives poured into the cities. In the second half of the century, the growth of cities slowed and in some cases even declined as the proportion of the population living in the suburbs increased.

In 1900, 8 of the 10 largest cities were northeastern or midwestern cities. Among the largest cities, San Francisco was the only western city, and Baltimore was the only southern city (see Appendix Table 4). New York, Chicago, and Philadelphia, the only cities with 1 million or more population in 1900, also were the only cities to rank among the 10 largest throughout the century.

Los Angeles and Detroit grew rapidly, and by 1930 had crossed the 1-million-or-more population threshold. By mid-century, Buffalo, San Francisco, and Cincinnati had dropped out of the group of the ten largest cities, and had been replaced by Los Angeles (ranked 4th), Detroit (5th), and Washington, DC (9th). (Pittsburgh ranked among the ten largest cities from 1910 to 1940.)

Over the last half of the century, the growth and change in the ten largest cities reflected the growth of the U.S. population in the Sunbelt. During this period, St. Louis, Boston, Baltimore, Cleveland, and Washington, DC, dropped out of the ten largest cities. They were either replaced by cities in Texas (Houston, Dallas, and San Antonio) or in the West (Phoenix and San Diego). None of the cities that fell from the list of the 10 largest ever reached 1 million population, while all the cities that replaced them passed the 1 million mark. In 2000, for the first time in U.S. history, a city (Detroit) declined from a population above 1 million to a population below 1 million.

Throughout the century, New York's population far exceeded the population of any other city, ranging from 3.4 million to 8.0 million. From 1900 to 2000 , its population was always at least double the population of the second largest city.

Chapter 2 AGE AND SEX COMPOSITION

## Chapter Highlights AGE AND SEX COMPOSITION

## National Trends

Past fertility trends exerted the strongest influence on the U.S. age structure in the 20th century. Relatively high fertility at the start of the century, lower fertility in the late 1920s and during the 1930s, higher fertility of the baby-boom period, followed by lower fertility of the baby-bust period, all affected the country's age composition.

At the beginning of the century, half of the U.S. population was less than 22.9 years old. At the century's end, half of the population was less than 35.3 years old, the country's highest median age ever.

Children under age 5 represented the largest 5-year age group in 1900 and again in 1950. By 2000, the largest 5 -year age groups were ages 35 to 39 years and 40 to 44 years, a large segment of the baby-boom generation.

During the last half of the century, the baby-boom generation's entry into an age group had a major impact on the growth of that age group. This effect on the age distribution will continue into the 21 st century. For example, rapid growth of the population age 65 and over will begin in 2011, when the first of the baby-boom generation reaches age 65, and will continue for many years.

The population age 65 and over increased tenfold during the century, from 3.1 million in 1900 to 35.0 million in 2000, compared with a twofold increase for the total population.

The proportion of the population age 65 and over declined for the first time in the 1990s, due partly to the relatively low number of births in the late 1920s and early 1930s.

Prior to 1950, the male population outnumbered the female population. From 1950 to 2000, the female population outnumbered the male population.

The sex ratio (males per 100 females) declined every decade from 1910 to 1980, then increased in the 1980s and the 1990s.

Central cities had lower sex ratios than suburban and nonmetropolitan areas.

Throughout the century, women represented most of the population age 85 and over, and their predominance in this age group greatly increased between 1900 and 2000.

## Regional Trends

From 1900 to 1960, the South had the highest proportion of children under age 15 and the lowest proportion of people 65 and over, making it the "youngest" region. The West had the highest percentage under age 15 in 1990 and 2000, and the lowest percentage 65 and over from 1970 to 2000.

Among the regions, the Northeast had the highest proportion age 65 and over for each census of the 20th century, except from 1910 to 1950, when the Midwest's proportion age 65 and over ranked highest.

The West had the highest sex ratio, and the Northeast had the lowest sex ratio among the regions for the entire century.

## State Trends

From 1900 to 2000, only Mississippi and Utah ranked among the ten states with the highest percentage of the population under age 15 in every decade.

Florida's rank in terms of percentage of the population 65 and over jumped from 42nd in 1900 to 1 st by 1970, and remained 1st through 2000, while its rank on percentage under age 15 fell from 14th in 1900 to 49th in 2000.

In 1900, Arkansas ranked as the 4th youngest state, but by the end of the century ranked as the 9th oldest. California changed in the opposite direction, moving from the 6th oldest state in 1900 to the 6th youngest state in 2000.

In 2000, only seven western states-Alaska, Colorado, Hawaii, Idaho, Nevada, Utah, and Wyoming-had a larger male population than female population.

## Chapter 2 AGE AND SEX COMPOSITION

The age and sex composition of the United States population changed considerably during the 20th century, as a consequence of fluctuations in births, deaths, and migration. Marriage patterns and changes in contraceptive use are among many factors affecting birth trends. Medical advances affecting mortality rates, especially infant mortality in the first part of the century and old age mortality in recent decades, also shaped the country's age structure. Laws and policies influencing international migration further contributed to U.S. age and sex composition in the past and continue to have an impact today.

In 1900, the U.S. population had an age and sex composition similar to many of today's developing countries. That is, the country was characterized by its "youngness." The median age (half of the population younger and half older) was about 23 years. Although the U.S. population aged during the century, with a median age of about 35 years in 2000, the extended length of the baby-boom period (1946 to 1964), plus the continued infusion of migrants kept the country's age structure younger than that of most developed countries of the world. Although the population in each 5-year age group increased numerically, younger age groups fell as a proportion of the total population, while the proportion in older age groups rose. Apart from these general trends, changes in age and sex structure varied from one decade to the next. Past U.S. fertility trends exerted the strongest influence on age composition. Low fertility from the late 1920s through the early 1940s, the post World War II baby boom, and a subsequent return to low fertility altered the composition of the U.S. population by age. The effect of the baby boom on the age and sex structure of the United States will extend several decades into the 21 st century as the baby boomers age through the life cycle.

Between 1900 and 2000, overall regional and state trends followed the basic U.S. trend. Regionally, the title of the "youngest" region shifted from the South to the West during the century, while that of the "oldest"
region shifted from the Midwest to the Northeast. States in the South and the West consistently ranked among the youngest and those from the Midwest and the Northeast among the oldest throughout the century. The relative changes in age structure were more pronounced in some states. In terms of percentage of population age 65 and over, Florida ranked 42 nd in 1900, but has ranked 1 st since 1970. Arkansas transformed from one of the ten youngest states in 1900 to one of the ten oldest in 2000. Conversely, California ranked among the ten oldest states at the beginning of the century, but ranked among the ten youngest states in 2000.

The United States gender composition shifted from a majority male population to a majority female population around midcentury. Larger gains for women than men in life expectancy and attrition of the large number of immigrants in decades prior to World War I (who were predominantly male) accounted for this shift. The West had the highest regional proportion of male population and the Northeast the highest proportion of female population during every decade of the 20th century. Only seven states, all in the West, still had a larger male than female population at the end of the century.

The graphics and text in this chapter depict the evolution of the number and proportional distribution of people in the United States by age and sex. These changes are described for the total population, regions, and states. Age trends focus on broad age groups, with particular emphasis on the population under age 15 and on the population age 65 and over. Trends in sex composition are discussed with the age distribution and separately by examining the trends in the relative numbers of the male and female populations at each age by region, state, and metropolitan status. Detailed data for each decade for the United States for 5 -year age groups by sex are provided in Appendix Table 5. Detailed data for the United States, regions, and states for the male and female population and for broad age groups are provided in Appendix Tables 6 and 7, respectively.

## At the beginning and the middle of the century, the most populous 5 -year age group was under age 5 . In 2000, people age 35 to 39 years outnumbered all other age groups.

The number of people in each age group grew during the course of the 20th century, but some age groups grew much more than others. The growth and the changing age and sex composition of the U.S. population can be portrayed through the use of population pyramids. The overall shape of the pyramid and the size of the bars for each age group depict the changes.
Both the male and female populations increased between 1900 and 1950 and again between 1950 and 2000 for every 5 -year age group. This is shown in the superimposed population pyramids in Figure 2-1.

Under age 5 represented the largest 5 -year age group in 1900, with a population of 9.2 million ( 4.6 million males and 4.5 million females). As Figure $2-1$ shows, each successive age group in 1900 was smaller than the preceding age group, creating the traditional pyramid shape or "broad-based" population.

In 1920, the largest 5 -year age group was still children under age 5, with a population of 11.6 million (see Appendix Table 5). The sizable decline in fertility starting in the 1920s and continuing through the Depression changed the age composition. By 1940,
the 15 -to-19 year age group (corresponding essentially to people born from 1920 to 1924) was the largest ( 12.3 million).

In 1950, as a result of the post-World War II baby boom (1946 to 1964), the group under age 5 was again the largest, with a population of 16.2 million. With each passing decade since 1950, the largest 5 -year age group has fallen in the range of ages that included the baby boomers. In 2000, the largest age groups were the 35 -to- 39 and 40 -to- 44 age groups (corresponding essentially to people born from 1960 to 1964 and 1955 to 1959, respectively). ${ }^{22}$

Further evidence of the impact of the baby boom on the U.S. age structure is seen in the measure of total population growth by age group from 1900 to 2000. The age groups 35 -to- 39 years, 40 -to- 44 years, and 45 -to-49 years experienced the largest increases in population of any age group from the beginning to the end of the century ( 17.7 million, 18.2 million, and 16.6 million, respectively).

[^21]Figure 2-1.
Total Population by Age and Sex: 1900, 1950, and 2000

[^22]
## Over the century, the age distribution of the U.S. population changed from relatively young to relatively old.

Changes in the U.S. age structure over the century may be illustrated by population pyramids where each bar represents the percentage of the total population in each age-sex group. ${ }^{23}$

The distribution of the population by age and sex in 1900 exhibits the classic pyramid shape, wider at the bottom and narrower at the top (see Figure 2-2). This broad-based shape characterizes a young, relatively high fertility population. In 1900, children under age 5 accounted for 12 percent of the U.S. population.

The general shape of the pyramid remained essentially the same into the 1920s, although declining fertility rates led to smaller proportions of the total population in the youngest age groups. By 1940, the base of the pyramid had taken on a more rectangular look. Younger age groups (under 5 through 29 years) still comprised a relatively large proportion of the population, but each 5year age group was roughly equal in size at 8 or 9 percent of the population, rather than exhibiting the steadily declining proportions by age of the 1900 pyramid.

[^23]By 1950, the onset of the baby boom altered the bottom of the pyramid, as 11 percent of the population was under age 5. Once again, the age-sex pyramid had a large base of very young people. The low fertility of the Depression years is evidenced by the "pinch" in the age structure, as people born during the 1930s were 10 to 19 years old.

The aging of the U.S. population in the second half of the 20 th century is shown by the more rectangular shape of the Census 2000 age-sex pyramid. The proportions do not begin to decline with each successive age group until after ages 35 to 39 years. Some variability in the pyramid's shape occurs in the 20-to-29 age group, where the slight "pinch" in the pyramid results from a relatively low number of births during the 1970s. Also, the baby-boom bulge appears in the 2000 pyramid in the 35 -to- 54 -age range.

Another feature of the 2000 age-sex pyramid is the less "cone-like" shape at the top of the pyramid compared with the 1900 and 1950 pyramids. The larger proportions of the population in older age groups in part result from sustained low fertility levels and from relatively larger declines in mortality at older ages in the latter part of the century.

Figure 2-2.
Age and Sex Distribution of the Total Population: 1900, 1950, and 2000

Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

# Population growth in broad age groups varied throughout the century, with major fluctuations due to changing fertility. 

The U.S. population in every age group at the end of the 20th century was much larger than at the start of the century. The decadal trends in specific broad age groups show that for some groups, such as ages 25 to 44 years, 45 to 64 years, and 65 and over, population increases occurred during every 10-year period (see Figure 2-3). In contrast, the under-15 age group and the 15-to-24-year age group experienced some population declines between censuses.

The population declines for people under age 15 from 1930 to 1940 and for people age 15 to 24 from 1940 to 1950 reflect the drop in fertility starting in the 1920s. Similarly, the population declines for those under age 15 from 1970 to 1980 and for those 15 to 24 from 1980 to 1990 result from the drop in fertility after the baby boom.

Large population increases from one decade to the next also are closely related to these fluctuations in
fertility. This is especially evident in the rapid increases in the population under age 15 in the 1950s, 15 to 24 years in the 1960s, 25 to 44 years in the 1970s and 1980s, and 45 to 64 in the 1990s (see Appendix Table 5). The entry of the baby-boom generation into each of these age groups yielded rapid population growth. The population age 65 years and over will begin to increase rapidly starting in 2011, when the first of the baby-boom generation reaches age 65, and the rapid growth of this age group will continue for two decades.

In 1900, the youngest broad age group (under 15 years) had the most members, and the oldest group (65 years and over) had the least. In 2000, the oldest group was still the smallest, but people age 25 to 44 and those age 45 to 64 outnumbered the population under age 15 years.

Figure 2-3.
Total Population by Broad Age Group: 1900 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## The share of the population under age 15 declined more than the share of any other broad age group.

Although the populations in the five broad age groups all increased in size over the course of the century, their proportional shares of the total population changed in different directions as a result of the different rates of growth for each group. In general, the shares of the population of the older age groups increased, while those of the younger age groups declined (see Figure 2-4).

The proportion of the U.S. population that was under age 15 declined more than the proportion of any other broad age group. At the beginning of the century, 1 out of every 3 people was under age 15 years. By 2000, only 1 of every 5 people was under age 15.
The total population share represented by 15-to-24 year olds generally declined from 1900 onward, reaching a low of 13 percent in 1960. This was followed by increases in the 1960s and 1970s, as the baby-boom cohort passed through this age group, and by declines as the baby-boom cohort moved out of the age group.

The share of the U.S. population represented by the age group 25 to 44 reached its lowest level of any
census during the 20 th century in 1970, and then increased over the next two decades to its maximum level in 1990. As with many of the changes in age structure experienced in the second half of the century, this trend largely reflects the entrance of the babyboom cohort into this age group.

Both the population age 45 to 64 years and the population age 65 years and over were at their lowest proportional levels of the U.S. total population at the beginning of the century. Their shares of the total population increased each decade until 1950 and 1990, respectively. After some fluctuation and decline, the proportion age 45 to 64 increased sharply in the 1990s, largely fueled by people born during the first half of the baby boom, and reached its highest level ( 22 percent) of the century in 2000. The decade of the 1990s was the first to show a decline in the proportion of the population age 65 and over, reflecting the relatively low number of births during the late 1920s and early 1930s.

Figure 2-4.
Percent Distribution of the Total Population by Age: 1900 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## The median age rose from 23 in 1900 to 35 in 2000 but declined between 1950 and 1970.

The median age ${ }^{24}$ of a population often is used to describe a population as "young" or "old." Populations with a median age under 20 years may be classified as relatively young, and those with a median age of 30 years or more as relatively old. The United States population aged over the course of the century, although not in each decade.

[^24]The median age rose gradually from 23 in 1900 to 26 in 1930 and then rose more rapidly to 29 in 1940 with the relatively small number of births during the 1930s (see Figure 2-5). After increasing to 30 in 1950, the median age fell, as a result of the baby boom, to 28 in 1970.

Beginning in the 1970s, lower fertility combined with the aging of the baby boom generation (the oldest turned age 30 in 1976), pushed the median age sharply higher. It reached 30 in 1980 -the same median age as in 1950-and continued to increase to a record high of 35 in 2000.

Figure 2-5.
Median Age: 1900 to 2000
(Years)

[^25]
## The population age 65 years and older increased more than tenfold between 1900 and 2000.

As discussed earlier, the United States population aged during the 20th century as the growth rate of the elderly ${ }^{25}$ population far exceeded the growth rate of the total population. In this century, the total population more than tripled, while the 65 years and over population grew more than tenfold, from 3.1 million in 1900 to 35.0 million in 2000 (see Figure 2-6).

The faster rate of growth of the elderly population increased its share of the U.S. population from 4.1 percent in 1900 to 12.6 percent in 1990 (see Figure 2-7). The 65 -to- 74 age group made up the majority of the 65 and over population throughout the century. In most decades, this age group also accounted for the largest share of the growth of the 65 and over population (see Appendix Table 5).

From 1900 to 1990, the elderly population grew faster than the total population in each decade, but between 1990 and 2000, for the first time in the history of the census, the 65 years and over population grew slower than the total population. ${ }^{26}$ During the 1990s, the total population increased by 13.2 percent, while the

[^26]population 65 years and over increased by only 12.0 percent. As a result, people age 65 and over represented a slightly smaller share of the U.S. population in 2000 ( 12.4 percent) than in 1990 ( 12.6 percent).

The declining proportion of the 65 and over population from 1990 to 2000 is directly related to the low fertility of the late 1920s and early 1930s. (People born during this period entered the 65 and over age group during the 1990s.) In particular, the population 65 to 69 years dropped from 10.1 million in 1990 to 9.5 million in 2000. The decline in the proportion of elderly in the population is expected to reverse as the baby boomers (born from 1946 to 1964) reach age 65, starting in 2011.

Among the elderly population, growth of the population 85 years and over is particularly notable, increasing from 122,000 in 1900 to 4.2 million in 2000. From 1940 to 2000, the 85 and over population increased at a more rapid rate than 65 -to- 74 year olds and 75 -to- 84 year olds in every decade.

The 85 and over age group also increased as a proportion of the elderly population, from 4 percent in 1900 to 12 percent in 2000, although they represented just 1.5 percent of the total U.S. population at the end of the 20th century.

Figure 2-7.
Percent of Total Population Age 65 and Over:
1900 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

# The South had the youngest regional age structure in the first half of the century but was replaced by the West by the end of the century. The Midwest generally had the oldest population during the first half of the century, and the Northeast had the oldest during the latter half. 

The trends in the proportions of people under 15 years old and those age 65 and over generally moved in opposite directions during the century. Every region's proportion of people under age 15 in 2000 declined substantially from its level in 1900, while the proportion of people 65 years and over increased (see Figure 2-8).

The proportion under 15 years fell from regional highs (in the Northeast, Midwest, and South) in the range of 30 percent to 40 percent in 1900 to lows of 20 percent to 23 percent in 1990 and 2000. However, the highest percentage under age 15 in the West occurred in 1960 rather than in 1900. The lowest regional percentage under age 15 occurred in 1990 or 2000 in every region.
Regional lows in the percentage 65 years and over occurred in 1910 in the Northeast and in 1900 for the other regions, and ranged from 3 percent in the South to 5 percent in the Northeast. Regional highs occurred in 2000 in the West and in 1990 for the other regions, and ranged from 11 percent in the West to 14 percent in the Northeast.

From 1900 through 1960, the South had the highest proportion of people under age 15 and the lowest
proportion of people age 65 and over, making it the "youngest" region (see Appendix Table 7). The highest percentage under age 15 resided in the Midwest in 1970, the South in 1980, and the West since 1990. The West had the lowest percentage 65 years and over from 1970 to 2000. The relative "youngness" of the South in the first half of the century was in part due to relatively higher fertility among Blacks, who represented a larger proportion of the South's population. Similarly, the relative "youngness" of the West's population in the latter part of the century is in part due to relatively higher fertility among Hispanics, who constituted a larger share of the region's population. Although the West had the highest percentage under age 15 since 1990, it had the lowest proportion of people in this age group from 1910 to 1930.

The Northeast had the highest regional proportion in the elderly group in 1900 but was replaced by the Midwest from 1910 to 1940. The Northeast returned to having the highest proportion age 65 and over in 1950 and remained the "oldest" region throughout the rest of the century.

Figure 2-8.
Percent Under Age 15 and Percent Age 65 and Over by Region: 1900 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## Mississippi's and Utah's populations ranked among the ten youngest in every decade of the 20th century.

While the U.S. population as a whole aged over the 20th century, many states remained relatively "younger" or "older" during the period. Still, every state and the District of Columbia had a lower percentage under age 15 in 2000 than in 1900. Similarly, every state had a much higher percentage age 65 and over in 2000 than 100 years earlier.

All ten states with the highest percentage under age 15 in 1900, 1950, and 2000 were in the South and the West. The regional composition of these youngest states shifted from nine in the South and one in the West in 1900 to four in the South and six in the West in 2000.

From 1900 to 2000, only Mississippi and Utah ranked among the ten states with the highest percentage of people under age 15 every decade (see Appendix Table 7). In 1900, 42 percent of Mississippi's population and 41 percent of Utah's population were under age 15 , ranking them second and ninth, respectively (see Table 2-1). By 2000, the percentage under age 15 in Mississippi had declined to 22 percent and in Utah to 27 percent. Even so, Utah had become the youngest state. South Carolina also ranked among the ten youngest states in the country for most of the century (1900 to 1980).

States in the Northeast and the Midwest tended to have relatively higher proportions of elderly ${ }^{27}$ people over the period 1900 to 2000 . These regions accounted for eight of the ten oldest states in 1900, all ten in 1950, and seven of the ten oldest in 2000. Three northeastern states, Maine, New Hampshire and Vermont and one midwestern state, lowa, ranked among the ten states with the highest percentage elderly for much of the century.

Florida's ranking in terms of percentage 65 and over jumped from 42nd in 1900 to 1st since 1970. Correspondingly, Florida's ranking of percentage under age 15 fell from 14th in 1900 to 49th in 2000. Arkansas and California also experienced marked changes in their relative "youngness" or "oldness." At the beginning of the century, Arkansas ranked as the fourth youngest state, but by the end of the century ranked as the ninth oldest. California changed in the opposite direction, moving from the sixth oldest state in 1900 to the sixth youngest state in 2000.
${ }^{27}$ For the purposes of this report, elderly refers to the population 65 years and over.

[^27]
# Prior to 1950, the male population outnumbered the female population. Since then, the female population has outnumbered the male population. 

A frequently used measure to summarize the balance between the male and female population is known as the sex ratio. ${ }^{28}$ A sex ratio of 100 indicates a balance between the male and female populations, ratios above 100 indicate a larger male population, and ratios below 100 indicate a larger female population. Figure 2-9 shows the trend in the sex ratio for the United States for every decade since 1900.

For each census from 1900 to 1940, the sex ratio was above 100. Males outnumbered females by a high of 2.7 million in 1910 but by only about 0.5 million in 1940 (see Appendix Table 6).

Several demographic factors contributed to the excess of males in the early part of the century. First, the influx of male immigrants to the United States at the turn of the century exceeded the influx of female immigrants. Also, younger populations tend to have higher sex ratios than older populations and the

[^28]United States, as discussed earlier, had a much younger population in the early part of the century. ${ }^{29}$

By the 1950 census, the sex ratio had dropped below 100. Over the next several decades, the numeric difference between the sexes continued to grow. The excess of the female population in the second half of the century ranged from 1.0 million in 1950 to 6.4 million in 1980 (see Appendix Table 6).

The sex ratio declined during every decade from 1910 to 1980. However, after declining to a low of 94.5 in 1980, the sex ratio increased in the following two decades to 96.3 in 2000. This is due to the fact that the male population increased at a more rapid rate than the female population during both the 1980s and 1990s. Higher net male than female immigration and relatively greater declines in male mortality rates contributed to this reversal of the downward trend in the sex ratio.

[^29]Figure 2-9.
Sex Ratio: 1900 to 2000
(Males per 100 females)

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

# While the shift to a larger female than male population occurred in every region, the West maintained the highest sex ratio of all U.S. regions throughout the century. 

While all four regions had similar trends in the sex ratio to that of the United States, they differed in the degree to which their male and female populations counterbalanced throughout the century (see Figure 210). The peak sex ratio for every region occurred in 1910, and the lowest ratio occurred in 1970 in the West, 1980 in the Northeast and the South, and 1990 in the Midwest.

Every region had relatively higher sex ratios during the first half of the century. The sex ratio in the Northeast and the South dropped below 100 during the 1930s, followed by the Midwest during the 1940s. The West, which did not have a larger female population until the 1960s, had the highest sex ratio among the regions for the entire century.

The sex ratios in the West in 1900 (128.1) and 1910 (128.9) were the highest of the 100 -year period. In general, the high ratios in the West during the first
several decades of the century reflect the "frontier" character of this region and both international and internal migration starting in the late 19th century of men who were attracted in part by employment opportunities in male-dominated industries, including mining and railroad construction.

During the entire century, the Midwest consistently had the second highest sex ratio (except for 1990), followed by the South, with the third highest sex ratio. The Northeast consistently had the lowest sex ratio of all U.S. regions.

The widest regional difference in the sex ratio occurred in 1900, when the sex ratio ranged from 100.0 in the Northeast to 128.1 in the West. The regional differences narrowed each decade, until 1970, when the sex ratio ranged from 92.5 in the Northeast to 97.7 in the West. In 2000, the sex ratio ranged from 93.5 in the Northeast to 99.6 in the West.

Figure 2-10.
Sex Ratio by Region: 1900 to 2000

[^30]
## The number of states with a larger female than male population quadrupled from 11 in 1900 to 44 in 2000.

As the century progressed, an increasing number of states had a larger female population than male population. In 1900, the female population exceeded the male population in only 11 states (including the District of Columbia), all in the Northeast or the South (see Figure 2-11).

By 1950, 27 states (including the District of Columbia) had a sex ratio below 100. The trend had spread into the Midwest as well as into more states in the Northeast and the South. All states in the West still had a sex ratio above 100 .

Between 1900 and 2000, the number of states with a larger female than male population quadrupled to 44 (including the District of Columbia). In 2000, only seven western states (Alaska, Colorado, Hawaii, Idaho, Nevada, Utah, and Wyoming) remained with a larger male population. ${ }^{30}$

The sex ratio of every state was lower in 2000 than in 1900. In other words, the female population had increased relatively more than the male population over the 100-year period. Despite this shift among all states toward a proportionately larger female population, Nevada and Wyoming maintained a sex ratio above 100 throughout the century (see Appendix Table 6). In addition, both Alaska and Hawaii have had an excess of males in every decade since their inclusion as states in the census of 1960. Massachusetts, North Carolina, Rhode Island, South Carolina, and the District of Columbia had larger female populations throughout the century.

[^31]Throughout the century, several states remained among the highest or lowest ranking in terms of their sex ratio. States consistently ranking among the highest included Idaho, Montana, Nevada, and Wyoming. Since the overwhelming majority of states had larger female than male populations by 2000, even some of the states with the highest-ranking sex ratios had proportionally larger female populations. Montana, for example, had a sex ratio of 99.3 in 2000. Only Massachusetts and the District of the Columbia remained among the ten states (or equivalent) with the lowest sex ratios for the entire century.

Prior to Alaska's statehood, either Nevada or Wyoming had the country's highest sex ratio every decade from 1900 to 1950. Once Alaska became a state, it had the highest sex ratio from 1960 through 2000. The sex ratio in Alaska steadily declined from 132.3 in 1960 to 107.0 in 2000.

Among the 50 states, Massachusetts had the lowest sex ratio every decade from 1900 through 1960.31 In 1970 and 1980, New York held this distinction. The state with the lowest sex ratio changed to Mississippi in 1990 and then to Rhode Island in 2000.

The gap between the highest and the lowest state sex ratios generally narrowed during the century. After 1910, the difference became smaller each decade until 1960, when the gap widened because Alaska was included as a state. The gap then continued to narrow each decade, reaching the smallest gap in the century in 2000, when the sex ratio ranged from a low of 92.5 in Rhode Island (89.0 in the District of Columbia) to 107.0 in Alaska.

# Central cities had relatively larger female than male populations compared with suburban and nonmetropolitan areas. 

Decennial data available by sex for metropolitan areas from 1950 to 2000 indicate that the sex ratio trend for metropolitan and nonmetropolitan areas followed a path similar to that of the United States as a whole. ${ }^{32}$ The sex ratio in both metropolitan and nonmetropolitan areas declined steadily from 1950 to 1980 (see Figure 2-12). The nonmetropolitan sex ratio remained stable from 1980 to 1990, whereas the metropolitan sex ratio followed the U.S. pattern of increasing sex ratios from 1980 to 1990 and again from 1990 to 2000.

The nonmetropolitan sex ratio exceeded the metropolitan sex ratio for the entire period from 1950 to 2000, indicating a greater predominance of the female population in metropolitan areas than in the nonmetropolitan population. In fact, in 1950 the male population in nonmetropolitan areas still outnumbered the female population, although the sex ratio in

[^33]the United States had already fallen below 100. Over the latter half of the century, the nonmetropolitan sex ratio ranged from 96.0 to 101.6 (in 1990 and 1950, respectively), and the metropolitan sex ratio ranged from 93.9 to 96.4 (in 1980 and 1950, respectively, see Appendix Table 16).

In 1950, there was a relatively large gap between the metropolitan and nonmetropolitan sex ratios, which steadily narrowed from 1950 to 1990. However, in the 1990s, the sex ratio in nonmetropolitan areas increased more than in metropolitan areas, widening the gap again.

Within metropolitan areas, sex ratios were much lower in central cities than they were in the suburbs. In the central cities, the sex ratio ranged from 90.7 in 1970 to 94.6 in 2000, which was its highest point in 40 years. In the suburbs, the sex ratio stayed within a narrow range during the period, from a low of 96.0 in 1980 to a high of 98.6 in 1960.

Figure 2-12.
Sex Ratio by Metropolitan Area Status: 1950 to 2000

Source: U.S. Census Bureau, decennial census of population, 1950 to 2000.

# Throughout the century, women represented most of the population age 85 and over, and the predominance of women greatly increased between 1900 and 2000. 

In the absence of migration, sex ratios tend to decrease with age due to higher male mortality rates at each age. ${ }^{33}$ The sex ratio at birth is about 105. Higher male mortality decreases the sex ratio, and the age at which the sex ratio drops below 100 (i.e., the female population exceeds the male population) depends on both the level of mortality and differences in age-specific mortality rates by sex. The predominance of women is most pronounced among the elderly and especially among the population 85 years and over.

While sex ratios in the United States for broad age groups largely reflect the typical pattern (see Figure 2-13), prior to 1960, U.S. sex ratios did not consistently decrease with age. In the early part of the century, the highest sex ratios occurred for the 45-to-64 age group, reflecting the predominantly male,

[^34]large-scale immigration in preceding decades. This age group had the century's highest sex ratio (115.2 in 1920). Since 1960, sex ratios by age have followed the expected pattern, with the highest sex ratio in the under 15 age group and steadily decreasing ratios for each subsequently older age group.

From 1920 to 1980, the sex ratios of the 45 to 64,65 to 84 , and 85 and over age groups all steadily declined. Generally, the declining sex ratios over time resulted from greater improvements in female mortality rates than in male mortality rates during these decades. The sex ratio for the under 15 age group remained fairly stable during the century, although slight, steady increases occurred during most decades.

From 1980 to 2000, the sex ratio increased for most age groups, except the 85 -and-over group, which had a declining sex ratio in the 1980s. In 1990, this group had the century's lowest sex ratio: 38.6, and during both decades women outnumbered men by more than 2-to-1.

Chapter 3
RACE AND HISPANIC ORIGIN

## Chapter Highlights

 RACE AND HISPANIC ORIGIN
## RACE

## National Trends

The United States population was much more racially diverse in 2000 than in 1900. At the beginning of the century, 1 out of 8 Americans was of a race other than White; at the end of the century, the ratio was 1 out of 4 .

The increased diversity in the United States was largely a phenomenon of the latter part of the century. Both the White population and the Black population represented a slightly smaller share of the U.S. total population in 1970 than they did in 1900.

From 1970 to 2000, the population of races other than White or Black grew considerably and, by 2000, was comparable in size to the Black population.

Among the races, the American Indian and Alaska Native population had the highest percentage under age 15 for most of the 20th century (peaking at 42 percent in 1960). In 2000, the Two or more races population (identified in Census 2000 for the first time) had the highest proportion (36 percent).

## Regional Trends

The Black population was concentrated in the South and the Asian and Pacific Islander population in the West from 1900 to 2000. However, these regional concentrations declined during the century.

The American Indian and Alaska Native population also was heavily concentrated in the West, and this concentration remained relatively stable throughout the century.

The South had the highest percentage of races other than White in every census from 1900 to 1980. The West had the highest percentage of races other than White in 1990 and 2000.

In the Northeast, the Midwest, and the South, Blacks constituted the largest share of the population of races other than White in every decade of the 20th century, while in the West, each of the races other than White represented the largest share during the century.

## State Trends

Increased racial diversity characterized most states during the 20th century. By 2000, 40 states and the District of Columbia had populations with at least 10 percent races other than White. The 10 states with 90 percent or more White in 2000 were: Idaho, Iowa, Kentucky, Maine, Montana, New Hampshire, North Dakota, Vermont, West Virginia, and Wyoming.

Only five states—Alabama, Arkansas, Mississippi, South Carolina, and West Virginia-had a lower percentage of races other than White in 2000 than in 1950.

## HISPANIC ORIGIN

## National, Regional, and State Trends

From 1980 to 2000, the Hispanic population (of any race) more than doubled.

More than 40 percent of the Hispanic population lived in the West from 1980 to 2000.

In every region, the percentage of Hispanics increased during the 1980s and again during the 1990s.

New Mexico had the highest proportion of Hispanics in its population of any state in 1980, 1990, and 2000. By 2000, 42 percent of New Mexico's population was Hispanic.

## MINORITY AND WHITE NON-HISPANIC

## National, Regional, and State Trends

The aggregated Minority population (people of races other than White or of Hispanic origin) increased by 88 percent between 1980 and 2000, while the White non-Hispanic population grew by only 7.9 percent during the 20-year period.

Younger age groups had a higher percentage of Minority population than did older age groups. By 2000, the percentage of Minority population ranged from 16 percent for people age 65 and over to 39 percent for those under age 25.

In 1980, more than 50 percent of the population in Hawaii and the District of Columbia was Minority. By 2000, California and New Mexico had also become more than 50 percent Minority, and Texas was the only other state with at least 40 percent Minority ( 48 percent).

## Chapter 3 <br> RACE AND HISPANIC ORIGIN

Racial and ethnic diversity increasingly characterized the population of the United States during the last half of the 20th century, especially in the last three decades of the century. Race and ethnicity are separate concepts as defined by the federal government. People of a specific race may be of any ethnic origin, and people of a specific ethnic origin may be of any race. Largescale immigration, primarily from Latin America and Asia, underlies both increased racial and ethnic diversity. In just the last two decades of the century, the Asian and Pacific Islander population tripled, and the Hispanic population more than doubled.

Every population census in the United States collected data on race, beginning with the first national enumeration in 1790 . The number of specific groups identified in a census generally increased over time. Census 2000 was the first U.S. census to allow individuals to identify themselves as being of more than one race. The trends by race in this chapter cover the following five groups: White, Black, American Indian and Alaska Native, Asian and Pacific Islander, and Some other race. For additional detail on the data on race included in this report, see Appendix C, Sources and Quality of Data.

The population of Hispanic origin is defined as another group for federal statistical purposes and may be of any race. Prior to 1970, determinations of Hispanic origin were only made indirectly, such as through questions on Spanish surname, or tabulating people who reported Spanish as their "mother tongue." The 1970 census was the first to include a question on Hispanic origin, but it was asked only for a 5-percent sample of all households. Beginning with the 1980 census, information on Hispanic origin was collected on a 100-percent basis. The analysis of trends in the Hispanic population in this chapter covers the period from 1980 to 2000. For additional detail on the data on Hispanic origin included in this report, see Appendix C, Sources and Quality of Data.

In general, Blacks, Asians and Pacific Islanders, American Indians and Alaska Natives, and Hispanics have represented increasing shares of the national population and of each region's population. The Black
share of the South's population, which declined from 32 percent in 1900 to 19 percent in 2000, is a notable exception. In 1900, only two non-Southern states (Nevada and Arizona) had populations with at least 10 percent races other than White but, by 2000, 26 non-Southern states had at least 10 percent races other than White, reflecting the spread of diversity across the country. By the end of the century, three states-California, Hawaii, and New Mexico-and the District of Columbia had more than 50 percent Minority populations (including Hispanics).

Data on age by race and Hispanic origin revealed increased "aging" of every population, but also important differences among the groups, showing Whites (and White non-Hispanics) and Asians and Pacific Islanders as relatively older groups and Blacks, Hispanics, and American Indians and Alaska Natives as relatively younger groups. Also, younger age groups consistently had higher levels of racial and ethnic diversity than older age groups.

The graphics and text in this chapter depict trends in the number and proportional distribution of the U.S. population by race from 1900 to 2000 and by Hispanic origin from 1980 to 2000. Changes in racial and ethnic composition are described for the total population, regions, and states. Trends in Hispanic origin, when discussed irrespective of race, are compared with the non-Hispanic population, and when discussed along with race, include the White non-Hispanic population trend for comparison. The chapter introduces data on changes in an aggregate Minority population, which pertains to the population of races other than White and people who are Hispanic, regardless of their race. In addition to examining trends in total size, proportional distribution, and geographic distribution by race and Hispanic origin, this chapter also examines age and sex composition trends and metropolitan concentration by race and Hispanic origin. Detailed data for each decade for the United States, regions, and states for individual race groups and for the population by Hispanic origin are provided in Appendix Tables 8, 9, and 10, and detailed data by age, race, and Hispanic origin for the United States are provided in Appendix Table 11.

# Since 1970, the population of races other than White or Black has grown significantly; however, Whites remained the largest race group. 

The White population continues to be the largest race group in the United States (see Figure 3-1). As recently as 1970, the U.S. population was nearly entirely classified as either White or Black, and the population of races other than White or Black was only 2.9 million, or 1.4 percent of the population. By 2000, the number of people in the United States who were of races other than White or Black had grown to 35 million, comparable in size to the Black population.

Numerically, the White population increased substantially in the 20th century. The White population grew from 66.8 million in 1900, exceeded 100 million by 1930, and passed the 200 million mark by 2000 . The combined population of all races other than White in 2000 was comparable in size to the White population at the beginning of the 20th century.

The Black population increased steadily throughout the century from 8.8 million in 1900 to about 4 times larger in 2000 ( 34.7 million people reported Black alone and 36.4 million people reported Black alone or in combination with one or more other races). Compared with the combined population of races other than White or Black, the Black population in 1960 was more than 10 times larger, in 1980 was slightly more than double, and in 2000 was of comparable size, reflecting the rapid growth of these other races in the United States.

Races other than White and Black include American Indian and Alaska Native, Asian and Pacific Islander, and Some other race (see Figure 3-2). ${ }^{34}$ For the first

[^35]time, Census 2000 also included a count of the number of people reporting two or more races, which at 6.8 million exceeded the American Indian and Alaska Native population.

The Asian and Pacific Islander and the Some other race (who are primarily Hispanic) populations particularly increased during the period from 1970 to 2000. International migration and subsequent births to the immigrant population contributed to this rapid population increase.

Within the groups comprising the races other than White or Black, Some other race was the smallest in 1970, but has been the largest group since the 1980 census. The size of this race group is greatly influenced by the overwhelming number of Hispanics who answer the question on race by reporting themselves as a specific Hispanic-origin group that is categorized as Some other race.

Figure 3-1 and Figure 3-2 show two values for the population of each race in Census 2000. The smaller value represents the number of people who reported belonging to that race alone and no other race, while the larger value represents the number of people who reported the specified race only, plus those who reported the specified race and one or more other races. These numbers may be thought of as representing the minimum-maximum range for the number of people in the particular race group. The basic trends in population size by race over the 20th century shown in Figure 3-1 and Figure 3-2 hold up, regardless of which value is used from Census 2000.

Figure 3-1.
Total Population by Race: 1900 to 2000

Note: For Census 2000, the lower value represents people reporting the specified race alone, while the
higher value represents people reporting the specified race, whether or not they reported any other races. Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

Figure 3-2.

# In 1900, about 1 out of 8 Americans was of a race other than White. By 2000, about 1 out of 4 Americans was of a race other than White. 

While the White population grew in every decade throughout the 20th century, its share of the total U.S. population did not follow this same pattern (see Figure $3-3$ ). Between 1900 and 1930, the percentage White of the U.S. population increased, while the percentage Black declined. Since then, the White share of the total population has decreased every decade, while the Black share has increased. ${ }^{35}$

People of races other than White or Black represented less than 1 percent of the U.S. population between 1900 and 1960. In recent decades, the share this group composed of the U.S. total increased greatly, from 1.4 percent in 1970 to 12.5 percent by 2000 .

Figure 3-4 illustrates the details of the rapid growth in races other than White or Black over the course of the century. Prior to 1950, all people in this broad grouping were reported as either American Indians and Alaska Natives or as Asians and Pacific Islanders. Beginning in 1950 and continuing for the remainder of the century, people could also be identified as Some other race. In 2000, the category Two or more races was used for the first time.

The American Indian and Alaska Native population and its share of the U.S. total increased each decade in the second half of the century, although its share represented about 1 percent in 2000. In contrast, the growth of Asians and Pacific Islanders and people in the Some other race category primarily accounted for

[^36]the large increase in the share of the U.S. population comprised of people of races other than White or Black.

Comparing the beginning and the end of the century, the United States in 2000 is clearly much more racially diverse than in 1900. At the beginning of the century, just 1 out of 8 Americans was of a race other than White. At the end of the century, the proportion was 1 out of 4. The decade-to-decade trend shows that this increasing diversity is largely a phenomenon of the second half of the century. As recently as 1970, the White population's share of the U.S. total was slightly smaller than at the beginning of the century. The Black population also represented a slightly smaller share of the U.S. total population in 1970 than in 1900, and even at the century's close, its share was less than 1 percentage point higher than in 1900.

The significant decline since 1970 in the White share of the U.S. population mainly resulted from the much faster growth of the Asian and Pacific Islander and the Some other race populations. The decline of 12.3 percentage points in the White share between 1970 and 2000 may be attributed to the following percentage point increases: 5.1 for Some other race; 3.1 for Asian and Pacific Islander; 2.4 for Two or more races (who may be any combination of the individual races, including combinations with White); 1.2 for Black; and 0.5 for American Indian and Alaska Native.

As noted previously, the increased shares for Asians and Pacific Islanders and Some other race may largely be explained by large increases in international migration and subsequent births to the immigrants for these groups. (The high immigration of Hispanics, who frequently are categorized as Some other race, and changes in the reporting of race by Hispanics account for much of the increase in the Some other race share of the total population.)

Figure 3-3.
Distribution of Total Population by Race:
1900 to 2000
(Percent)

Note: In 2000, the percent distribution is based on the reporting of race alone for Whites and Blacks.

## Percent Races Other Than White or Black by Race: 1900 to 2000 <br> (Percent of total population)

[^37]
## The Hispanic population more than doubled in size from 1980 to 2000.

The Hispanic population includes people who may be of any race. ${ }^{36}$ As discussed earlier, the 1980 census was the first to include a separate question on Hispanic origin asked of every individual in the United States. ${ }^{37}$

The Hispanic population more than doubled in size from 1980 to 2000 (see Figure 3-5). In 1980, there were 14.6 million Hispanics in the United States. From 1980 to 1990, they grew by 7.7 million people, or 53 percent, to 22.4 million, and in the next decade the growth rate was even higher. During the 1990s, the Hispanic population increased by 13.0 million people,

[^38]or 58 percent, reaching a population of 35.3 million at the century's close.

Overall, the Hispanic population grew by 20.7 million people from 1980 to 2000. High levels of immigration contributed to this rapid growth, coupled with relatively high fertility levels.

The much more rapid growth of the Hispanic population relative to the non-Hispanic population increased the Hispanic share of the total population in both decades. In 1980, Hispanics constituted 6.4 percent of the total population. By 1990, their share had increased to 9.0 percent, and during the 1990s, their share increased by an additional 3.5 percentage points, so that by 2000, Hispanics represented 12.5 percent of the U.S. population, nearly twice the proportion than just 20 years earlier.

Figure 3-5.
Hispanic Population and Percent Hispanic of Total Population: 1980 to 2000

## The White population grew more slowly than every other race group in the second half of the 20th century and for the century as a whole.

By the end of the 20th century, the fact that the U.S. population had become increasingly diverse was generally well-known. However, when the century is split into halves, this conventional wisdom does not entirely hold true. The White population grew at a lower rate, on average, than each of the other race groups for the periods 1900-2000 and 1950-2000 (Figure 3-6), when some groups grew many times faster. However, during the first half of the century, the White population grew at a faster rate than either the Black population or the American Indian population.

The trend in the average annual growth rates by race moved in an opposite direction for Whites compared with every other race. That is, the White population had a higher average annual growth rate ( 1.4 percent) during the first half of the century than during the second half ( 0.9 percent), while the 50 -year average annual growth rate for each of the other races was higher in the second half of the century.

Among races with available data throughout the century, Asians and Pacific Islanders grew faster than the other groups in both halves of the 100-year period. This high growth rate resulted from a combination of considerable immigration and a relatively small population
size. American Indians and Alaska Natives increased at the slowest rate of the groups in the first half of the century, but grew rapidly during the latter period, a statistical change that is partly due to changes in reporting. The growth rate of the Black population, which is much less influenced by immigration, increased from an average rate of 1.1 percent in the first half of the century to 1.7 percent in the second half.

The "other race" category (not shown) had the highest growth rate during the century: an average annual increase of 9.9 percent from 1950 to 2000 . In part, this high rate of growth resulted from the fact that the Hispanic population increased rapidly during this period and a large proportion of the responses of Hispanics to the question on race were categorized as Some other race (beginning in 1980), since the number of Hispanics is determined from a separate question. Another contributing factor is the small population size of the "other race" category in 1950. ${ }^{38}$

[^39]Figure 3-6.
Average Annual Growth Rate by Race: 1900-1950, 1950-2000, and 1900-2000

${ }^{1}$ The rate excludes Alaska and Hawaii at the beginning date and includes Alaska and Hawaii at the ending date. This has the effect of increasing the rate, particularly for American Indians and Alaska Natives and for Asians and Pacific Islanders.
Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

# The Minority population grew 11 times as rapidly as the White non-Hispanic population between 1980 and 2000. 

Immigration and subsequent births to the new arrivals during the last few decades of the century played a major role in changing the racial and ethnic composition of the U.S. population. These influences are indicated by the very high percentage increases in the Asian and Pacific Islander (204 percent) and the Hispanic (142 percent) populations from 1980 to 2000 (see Figure 3-7).

Considering race without regard to Hispanic origin, the White population grew slower than every other race. The rapid growth of the Some other race population was strongly influenced by the large number of people in this group who are Hispanic. (For example, Census 2000 results showed that 97 percent of the population who reported Some other race alone were Hispanic. $)^{39}$ The high percentage change of the American Indian and Alaska Native population in part may be attributed to a higher tendency among

[^40]respondents to report as this race in Census 2000 than in 1980, as well as changes in methodology and improvements in coverage of this population.

Considering Hispanic origin without regard to race, Hispanics grew much faster than non-Hispanics. Combining race and Hispanic origin, the White nonHispanic population grew by only 7.9 percent between 1980 and 2000, while the aggregated Minority population (people of races other than White and people of every race who were of Hispanic origin) increased 11 times as fast ( 88 percent) during the 20-year period.

Among all the population groups shown in Figure 3-7, only the White, the non-Hispanic, and the White nonHispanic populations grew more slowly than the total population. The higher percentage increases for each individual race other than White and for the Hispanic population produced a high percentage growth for the Minority population, resulting in an increase in the Minority share of the U.S. population from 20 percent in 1980 to 31 percent in 2000 and a corresponding decrease in the White non-Hispanic share.

Figure 3-7.
Percent Change in Population Size by Race and
Hispanic Origin: 1980-2000

Source: U.S. Census Bureau, decennial census of population, 1980 and 2000.

# Blacks, along with Asians and Pacific Islanders, have been the most regionally concentrated races. More than half of Blacks still live in the South and, until 2000, more than half of Asians and Pacific Islanders lived in the West. 

The population of each race was not evenly distributed across the regions of the United States in the 20th century (see Figure 3-8). The trend in the distribution of the White population by region most closely mirrored the regional distribution of the total U.S. population. This, of course, reflects the fact that the White population represents such a large percentage of the U.S. population.

The Black, Asian and Pacific Islander, and American Indian and Alaska Native populations all exhibited strong regional concentrations. Each race also followed quite different decade-to-decade trends in their regional distributions.

The Black population was, and continues to be, concentrated in the South. However, the extent of this concentration diminished considerably during the 20th century. For the first two decades of the century, nearly 9 out of 10 Blacks lived in the South. In 1940, over three-fourths of the Black population lived in the South. After World War II, the percentage of the Black population in the South declined more rapidly, reflecting the effect of substantial Black migration, especially to large metropolitan areas in the Midwest and Northeast. This migration contributed to the corresponding rise in the proportion of the Black population in these regions through 1970. This trend generally reversed toward the end of the century. By 2000, the Northeast's and the Midwest's shares of the Black population had dropped below their shares in 1970, while the South's share had increased. Throughout the century, the West had the smallest share of the Black population Even though the West's share of the Black population increased every decade from 1900 to 1990, by the end of the century fewer than 10 percent of all Blacks lived in the West.

The Asian and Pacific Islander population also had a strong regional concentration, particularly in the first half of the century. During the period 1900 to 1940 , about 4 out of 5 Asians and Pacific Islanders lived in the West. The proportion in the West dropped significantly between 1940 and 1950, primarily due to a decline in the Japanese population in California, Washington, and Oregon and a corresponding increase in the Japanese populations in Illinois (increasing the Midwest's share) and in New York, New Jersey, and Pennsylvania (increasing the Northeast's share). The sharp increase in the West's share from 1950 to 1960 resulted from the addition of Hawaii as the 50th state.

As with the Black population, the regional concentration of Asians and Pacific Islanders diminished during the century. The Northeast's and the South's shares of Asians and Pacific Islanders increased rapidly during this period, with the Northeast's share ranking 2nd among the regions and the South's share surpassing the Midwest's, although the Midwest's share also generally rose in the last half of the century.

The American Indian and Alaska Native population also was characterized by concentration in the West. In contrast to the trends of other races, however, their regional distribution remained fairly stable throughout the century. Of the total U.S. population of American Indians and Alaska Natives, the Northeast had the lowest proportion, and, with the exception of 1950, the South had the 2nd highest share.

# The percentage of races other than White was highest in the South from 1900 to 1980 and highest in the West since 1990. 

During the first half of the 20th century, the population of races other than White composed 5 percent or less of the total population in the Northeast, the Midwest, and the West (see Figure 3-9). In contrast, the South had much higher percentages of races other than White during this period, even though this percentage declined each decade, from a high of 33 percent in 1900 to 22 percent in 1950.

The South differed from the other regions in both the level and trend of the percentage of races other than White. In terms of the level, the South had the highest percentage of races other than White during every decade 1900 to 1980. During the second half of the century, the rapid growth of races other than White in the West made it the region with the highest percentage of races other than White in 1990 and 2000. The percentage of people other than White in the Northeast's population increased every decade, as it did in the Midwest (except from 1900 to 1910). The West experienced little change until 1940, but increased every decade thereafter. The South's share of its population represented by races other than White declined every decade from 1900 to 1970 and the percentage White increased. From 1970 to 2000, the percentage of races other than White increased in every region.

As the percentage of races other than White in the South declined, the corresponding percentages in other regions increased, narrowing the differences between the regions. The widest gap occurred in 1900, when the percentage of races other than White ranged from a low of 1.9 percent in the Northeast to 32.6 percent in the South. The gap narrowed each succeeding decade, reaching the smallest regional difference in 1980, when the percentage of races other than White ranged from 11.3 percent in the Midwest to 21.8 percent in the South. Since 1980 the gap widened, as the increase in the percentage of races
other than White in the West exceeded the increase in the other regions.

The specific racial composition of the population of races other than White also differed by region. In the Northeast, the Midwest, and the South, Blacks constituted the largest share of races other than White in every decade of the 20th century. However, in the West, American Indians and Alaska Natives represented the largest share in 1900, Asians and Pacific Islanders the largest share from 1910 to 1940, Blacks the largest share from 1950 to 1970, and Some other race (which is nearly all Hispanic) represented the largest share from 1980 to 2000.

While Hispanics may be of any race, a sizable proportion are classified as Some other race. (The question on race is separate from the question on Hispanic or Latino origin). The high growth rate of the Hispanic population since 1980 is reflected by the relatively high share that the "Some other race" group represents of the total percentage of races other than White. Since 1980, the share of Some other race exceeded the shares of Asians and Pacific Islanders and American Indians and Alaska Natives in every region.

Census 2000 was the first to include the option for individuals to identify themselves as more than one race. Among the regions, the percentage of the population categorized as Two or more races ranged from 1.6 percent in the Midwest to 4.3 percent in the West. In Figure 3-9, the totals for the percentage in each specific race group for 2000 represent those people who reported that specific race alone. Those who reported any specific race in combination with any other race (including people who reported White as one of the races) are shown in the Two or more races category. In every region, the percentage of the population of Two or more races exceeded the percentage American Indian and Alaska Native.

West

19001910192019301940195019601970198019902000 Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## While the Hispanic population was concentrated in the West, the percentage Hispanic increased in every region from 1980 to 2000.

The regional distribution of the Hispanic population remained relatively stable from 1980 to 2000. The majority of Hispanics lived in the South and the West, with smaller proportions living in the Northeast and the Midwest, respectively.

More than 40 percent of the Hispanic population lived in the West from 1980 to 2000 (see Figure 3-10). This reflects the fact that all the states along the U.S.Mexico border (except Texas) are western states and most of the Hispanic population is Mexican in origin. From 1980 to 1990, the proportion of Hispanics living in the West increased from 43 percent to 45 percent and then declined to 43 percent in 2000.

A slightly higher proportion of Hispanics lived in the South in 2000 (33 percent) than in 1980 (31 percent). In 2000, more than three-quarters of the Hispanic population lived in the South or the West. ${ }^{40}$

The Northeast was the only region in the United States with a steadily declining share of Hispanics, dropping from 18 percent in 1980 to 15 percent in 2000.

Hispanics were least likely to live in the Midwest. Although their share increased from 1990 to 2000
${ }^{40}$ See U.S. Census Bureau, 2001c, The Hispanic Population: 2000, by Betsy Guzmán.
after dropping during the 1980s, fewer than 1 of 10 Hispanics lived in the Midwest at the century's close.

While the regional distribution of Hispanics did not change very much between 1980 and 2000, their total numbers and proportion of each region's population increased during both the 1980s and the 1990s in every region (see Figure 3-11).

The West had the highest proportion of Hispanics of any region from 1980 to 2000, rising rapidly from 14 percent of the region's population in 1980 to 24 percent in 2000. The West was the only region in which the proportion of Hispanics exceeded the national level (see Appendix Table 10).

The proportion of Hispanics in the South's population nearly doubled from 5.9 percent in 1980 to 11.6 percent in 2000. Although the South's proportion of Hispanics ranked 2 nd among the regions, its proportion at the end of the century was less than half the proportion Hispanic in the West.

The Northeast and the Midwest had the smallest proportions of Hispanics in their populations, less than 10 percent and less than 5 percent, respectively, in 2000.

Figure 3-10.

Percent Hispanic of Regional Population: 1980 to 2000

Source: U.S. Census Bureau, decennial census of population, 1980 to 2000.

## The percentage Minority increased rapidly in every region since 1980 , especially in the West.

The increasing racial and ethnic diversity of the U.S. population in the 20th century has largely been a post1970 development, with regional patterns generally reflecting the trend of the United States as a whole. From 1980 to 2000, the percentage Minority ${ }^{41}$ markedly increased in every region, and each region's per-centage-point increase was larger in the 1990s than in the 1980s (see Figure 3-12).

Each region's rank according to its percentage of Minority population remained the same from 1980 to 2000. At each census, the West had the highest percentage Minority, followed by the South, the Northeast, and the Midwest.

In 1980, the percentage Minority in the West (27 percent) narrowly exceeded the percentage Minority in the South (26 percent). Since 1980, the West has experienced an especially rapid increase in its percentage

[^41]Minority, and the difference between the West and the other regions widened. In 2000, the Minority population represented 42 percent of the total population of the West and 34 percent of the population of the South.

The lack of data on Hispanic origin precludes calculating the percentage Minority for most of the century. However, since the Black population represented, by far, most of the Minority population during this period, the South would have ranked as the region with the highest percentage Minority during the first half of the century.

From 1980 to 2000, percentage-point increases in the percentage Minority in the Northeast exceeded those of the Midwest. By 2000, the Minority population in the Northeast had grown to 27 percent, comparable to the West and the South two decades earlier. Although the percentage Minority increased rapidly in the Midwest in the 1990s, it remained less than half that of the West in 2000 (19 percent and 42 percent, respectively).

Figure 3-12.
Percent Minority by Region: 1980 to 2000

Source: U.S. Census Bureau, decennial census of population, 1980 to 2000.

# From 1900 to 2000, the number of non-Southern states with populations of at least 10 percent races other than White increased from 2 to 26. 

At the beginning of the century, less than 10 percent of the people in most states were of races other than White. Nevada and Arizona had the only populations outside of the South with at least 10 percent races other than White. In contrast, the population of every Southern state, except West Virginia, had at least 10 percent races other than White (see Figure 3-13). The percentage of races other than White in the Southern coastal states stretching from Virginia to Louisiana exceeded 30 percent. In two of these states, Mississippi and South Carolina, the majority of the population was races other than White in 1900.

By 1950, the state pattern of the percentage of races other than White had changed little. Arizona was the sole non-Southern state with more than 10 percent races other than White. The number of Southern states with less than 10 percent races other than White increased to include Kentucky and Oklahoma, in addition to West Virginia. While the percentages in 1950 were still relatively high in the South, they had declined in every Southern state except West Virginia. ${ }^{22}$

The increased diversity of the United States that occurred between 1950 and 2000 is evident from the state map for 2000 shown in Figure 3-13. By 2000, only 10 states had populations with less than 10 percent races other than White: Idaho, Iowa, Kentucky, Maine, Montana, New Hampshire, North Dakota, Vermont, West Virginia, and Wyoming. In the other 40 states, the percentage ranged from 10 percent in

[^42]Nebraska to 76 percent in Hawaii. The District of Columbia's population had 69 percent races other than White.

At the end of the century, states with relatively higher percentages (20 percent or more) of races other than White were generally coastal and U.S-Mexican border states, extending south from New York and across the southern and southwestern states to California. States in the South still had relatively high percentages of races other than White at the century's close and were joined by several states outside the region. In 1900 and 1950, no state outside the South had at least 30 percent races other than White. ${ }^{43}$ In 2000, five nonSouthern states-Alaska, California, Hawaii, New Mexico, and New York-each had over 30 percent races other than White.

Across the country and in most states, the proportions of people other than White increased during the course of the century. Although all Southern states except West Virginia had a lower percentage of races other than White in 1950 than in 1900, their proportions remained at a high level. In nearly all states, the percentage of races other than White was higher in 2000 than in 1950. The five exceptions were: Alabama, Arkansas, Mississippi, South Carolina, and West Virginia, where the percentage of races other than White was lower in 2000 than in 1950, so, their percentage White was higher at the century's end than at midcentury.
${ }^{43}$ Alaska and Hawaii were not included in the calculations prior to statehood. If included from 1900 to 1950, Hawaii would have had more than 30 percent races other than White in every census and Alaska in each census from 1900 through 1940.

Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

# The ten states with the highest percentage Black were all in the South in 1900, 1950, and 2000; no state in the Northeast ranked among the ten highest in percentage American Indian and Alaska Native; and while the ten states with the highest percentage Asian and Pacific Islander were all in the West in 1900, every region was represented by 2000. 

Previous discussion of the increased diversity of the U.S. population as measured by the percentage of people who are races other than White showed that this diversity is becoming widespread throughout the 50 states. At the same time, examination of the states with the highest percentages of their populations in specific race groups reveals that some groups remained concentrated in particular states throughout the century (see Table 3-1).

Among the 50 states, Mississippi had the highest percentage of Blacks in its population in every decade, 1900 to 2000. (The District of Columbia, treated as a state equivalent for statistical purposes, has ranked first in percentage Black since 1960.) In 1900, 1950, and 2000, all ten states (including the District of Columbia) with the highest percentages Black were in the South.

In 1900, Blacks constituted the majority in Mississippi and South Carolina and remained more than 50 percent of the population in these states until 1930 and 1920, respectively (see Appendix Table 8). The population in the District of Columbia has been 50 percent or more Black since 1960. The highest-ranking states in percentage Black in 1950 were the same as in 1900, although the ranking shifted among the states. In 2000, 8 of these 10 states were still among the top ten in percentage Black, and Maryland and Delaware had replaced Florida and Arkansas.

The states with the highest percentage of American Indians and Alaska Natives in their populations have also generally remained the same throughout the century. Eight of the ten states with the highest percentage American Indian and Alaska Native in 1900 were also among the ten highest in 1950 and in 2000.

Washington dropped out of the ten highest-ranked states by 1950, replaced by Utah. However, by 2000, Utah dropped out of the ten highest-ranked states, along with Nevada, and they were replaced by Washington, which reentered the ten highest-ranked states, and by Alaska, which was not ranked prior to statehood. (If Alaska were included, it would have ranked 1 st among all states in the percentage of population American Indian and Alaska Native throughout the century.) The Northeast was the only region without a state ranked among the 10 highest percentages American Indian and Alaska Native during the century.

The changes in the rankings of states according to their percentage Asians and Pacific Islanders varied more than the changes in rankings for Blacks and American Indians and Alaska Natives. In 1900, the states with the ten highest percentages of Asians and Pacific Islanders were all in the West. Of these ten, only California, Nevada, and Washington also were among the ten highest in 1950 and 2000. In 1950, 9 of the 10 highest-ranking states were still in the West, with only the District of Columbia outside the region. However, by the end of the century, the number of Western states among the ten highest had fallen to five, which were joined by the southern states of Maryland and Virginia and by the northeastern states of Massachusetts, New Jersey, and New York. Alaska and Hawaii each ranked among the ten highest states in percentage Asian and Pacific Islander in 2000. (Neither state was ranked prior to 1960, the first census after they became the 49th and 50th states, respectively. However, Hawaii would have ranked 1 st among all states in the percentage of population Asian and Pacific Islander if it had been included.)

Table 3-1.
Ten States With the Highest Percents Black, American Indian and Alaska Native, and Asian and Pacific Islander: 1900, 1950, and 2000

| Rank | 1900 |  | 1950 |  | 2000 |  |

## Hawaii had the highest percentage ( 21 percent) of people who reported as more than one race in 2000.

Census 2000 was the first time individuals were allowed to identify themselves as more than one race in the history of census-taking in the United States. Of the total population ( 281.4 million) in $2000,6.8$ million people, or 2.4 percent, reported as more than one race. Regionally, the West had the highest number ( 2.7 million) and the highest proportion (4.3 percent) of people of two or more races.

Among the states, Hawaii had, by far, the largest percentage (21.4 percent) of its population reporting more than one race. Only three other states-Alaska ( 5.4 percent), California ( 4.7 percent) and Oklahoma ( 4.5 percent)-had 4.0 percent or more of their populations reporting more than one race (see Figure 3-14). In fourteen states, the percentage reporting more than one race exceeded the U.S. level of 2.43 percent. ${ }^{44}$ In

[^43]addition to the four states already named, the other ten were: Arizona, Colorado, Nevada, New Jersey, New Mexico, New York, Oregon, Rhode Island, Texas, and Washington.

Most states (36) and the District of Columbia had lower percentages reporting as more than one race than the overall United States percentage. Twenty-five of these states were in the 1 percent to 2 percent range, while 6 states and the District of Columbia ranged from 2 percent up to the U.S. level ( 2.43 percent). In five states (four of which are in the South), less than 1 percent of the population reported being more than one race: Alabama, Maine, Mississippi, South Carolina, and West Virginia.

The three states with the largest populations, California, Texas, and New York, were also the three states with the largest numbers of people reporting two or more races ( 1.6 million, 515,000 and 590,000, respectively, see Appendix Table 9).

Source: U.S. Census Bureau, Census 2000 Summary File 1.

# In 1980, Colorado was the only state not bordering Mexico which had an Hispanic population of at least 10 percent. By 2000, five more nonborder states had populations which were at least 10 percent Hispanic. 

In every state except Hawaii, the percentage of the population that was Hispanic increased during the 20year period from 1980 to 2000. The percentage Hispanic in Hawaii decreased by less than 1 percentage point and Hawaii was among the top 20 states in terms of its percentage of Hispanic population (see Appendix Table 10).

The number of states with populations of at least 10 percent Hispanic doubled from five to ten between 1980 and 2000. In 1980, only Arizona, California, Colorado, New Mexico, and Texas had populations that were at least 10 percent Hispanic (see Figure 3-15). By 1990, three more states, Florida, New York, and Nevada, were added to the list. In 2000, the number of states with populations that were at least 10 percent Hispanic increased to ten, with the addition of Illinois and New Jersey.

In 1980, New Mexico was the only state in which Hispanics represented at least one-fourth of its population. By 2000, Hispanics made up at least 25 percent of the population in three additional states (Arizona, California, and Texas). All four of these states are on the U.S.-Mexico border.

In 1980, Colorado was the only state with a 10 percent or greater Hispanic population that did not share a border with Mexico. By 2000, Hispanics represented at least 10 percent of the population in five additional nonborder states: Florida, Illinois, Nevada, New Jersey, and New York.

The states with the highest proportion of Hispanics were concentrated primarily in the West. In 1980, 7 of the 12 states that were at least 5 percent Hispanic were in the West. Nearly all of the states in the Midwest, the South, and the Northeast had less than 5 percent Hispanic in their populations. However, four states outside the West (Florida, New Jersey, New York, and Texas) ranked among the ten states with the highest percentages of Hispanics from 1980 to 2000. By 2000, the proportions of Hispanics among the midwestern states remained relatively low. Illinois was the only state in the Midwest with Hispanics representing at least 10 percent of its population.

New Mexico had the highest proportion of Hispanics in its population of any state in 1980, 1990, and 2000 (see Appendix Table 10). More than one-third of New Mexico's population was Hispanic in 1980. By 2000, 42 percent of its population was Hispanic.

Following New Mexico in terms of percentage Hispanic were Texas and California. In 1980, Hispanics represented 21 percent of Texas' population and 19 percent of California's. In 1990, California surpassed Texas with a slightly higher proportion of Hispanics. In 2000, California and Texas remained ranked second and third, respectively, in terms of percentage Hispanic, with Hispanics making up nearly a third of their populations.

Figure 3-15.

Percent Hispanic by State: 1980 and 2000

Source: U.S. Census Bureau decennial census of population, 1980 and 2000.

# Among the 50 states, Hawaii, New Mexico, Mississippi, Texas, and California had the $\mathbf{5}$ highest percentage Minority populations from 1980 to 2000. 

As noted earlier, between 1980 and 2000 the White non-Hispanic population of the United States increased much less than the aggregated Minority (people of races other than White or of Hispanic origin) population ( 7.9 percent and 88 percent, respectively). The more rapid increase of the Minority population results in this collective group representing a larger share of the total population. The faster growth of the Minority population occurred in all 50 states. Thus, the percentage Minority increased in each of the 50 states between 1980 and 2000. (The percentage Minority in the District of Columbia declined from 74 percent in 1980 to 72 percent in 2000).

Figure 3-16 illustrates the widespread shift to higher proportions of Minority population throughout the United States during the 20-year period, 1980 to 2000. In 1980, 21 states had populations with less than 10 percent Minority. By 2000, the number of such states had dwindled to 6-lowa, Maine, New Hampshire, North Dakota, Vermont, and West Virginia. The number of states with 30 percent or higher percentage Minority population doubled, from just 8 states (including the District of Columbia) in 1980 to 17 states in 2000. In 1980, all 8 states with 30 percent or more Minority populations were in the West or the South. These two regions also accounted for 6 of the 9 states added to this category in 2000, the remaining being Illinois, New Jersey, and New York.

Over time, several state populations became "majority Minority." In 1980, only Hawaii and the District of Columbia had populations with more than 50 percent Minority. By 2000, California and New Mexico had also become majority Minority. Texas, with 48 percent Minority in 2000, was the only other state with at least 40 percent Minority.

Among the 50 states, the percentage-point increases from 1980 to 2000 in the Minority population ranged
from 1 percentage point in West Virginia to 20 percentage points in California. ${ }^{45}$ The Minority population share rose by 10 percentage points or more in 14 states. After California, the next largest increases were in Nevada (18 percentage points), and Texas, New Jersey, and New York (13 percentage points each). The Minority population share in the remaining nine states with substantial percentage-point increasesArizona, Connecticut, Florida, Illinois, Massachusetts, Maryland, Oklahoma, Rhode Island, and Washingtonall increased by 10 to 12 percentage points.

The large increases in the percentage Minority during the period 1980 to 2000 occurred across all categories in states with relatively low, moderate, and high initial levels of percentage Minority in 1980. For example, the Minority population shares in Massachusetts, Rhode Island, and Washington each increased by at least 10 percentage points, yet all had less than 10 percent Minority in 1980. At the same time, California and Texas also had large increases in their Minority population shares, even though they already ranked among the states with the highest shares in 1980.

The District of Columbia had the highest percentage Minority in 1980. In 2000, Hawaii (77 percent) had the highest Minority population share. Among the 50 states, Hawaii, New Mexico, Mississippi, Texas, and California had the 5 highest percentages Minority in both 1980 and 2000. In 1980, the percentage Minority in these states ranged from 33 percent in California to 69 percent in Hawaii. At the end of the century, the Minority share in these states ranged from 39 percent in Mississippi to 77 percent in Hawaii. In 1980, Vermont had the lowest Minority share ( 1.5 percent). At the century's close, Maine had the lowest percentage Minority (3.5 percent).
${ }^{45}$ The percentage Minority is equivalent to 100 minus the percentage White non-Hispanic (see Appendix Table 10).

Source: U.S. Census Bureau, decennial census of population, 1980 and 2000.

# From 1970 to 2000, Asians and Pacific Islanders were most likely, and American Indians and Alaska Natives were least likely, to live in metropolitan areas. 

The percentage of each race and Hispanic origin group living in metropolitan areas increased every decade from 1960 to 2000 (see Figure 3-17). This trend follows the U.S. pattern of an increasing share of the total population living in metropolitan areas over the course of the century.

The percentage metropolitan for each group increased, and every race and ethnic group maintained its relative ranking every decade. For censuses with available data, Asians and Pacific Islanders have been most likely, and American Indians and Alaska Natives least likely, to live in metropolitan areas. By 2000, nearly 96 percent of all Asians and Pacific Islanders lived in a metropolitan area (see Appendix Table 16). In contrast, the American Indian and Alaska Native population lived primarily in nonmetropolitan areas before the 1990 census, when a majority ( 51 percent) lived in metropolitan areas for the first time.

After Asians and Pacific Islanders, Hispanics had the second highest proportion living in metropolitan areas. From 1980 to 2000, the percentage of Hispanics living in a metropolitan area increased from 88 to 91 percent.

In 1960, 65 percent of Blacks and 63 percent of Whites lived in metropolitan areas. The shares of the Black and the White populations living in metropolitan areas increased every decade, 1960 to 2000, but the gap grew wider every 10 years. By 2000, the difference widened to 8 percentage points, with 86 percent of Blacks and 78 percent of Whites living in a metropolitan area.

Although American Indians and Alaska Natives consistently had the least likelihood of living in a metropolitan area from 1970 to 2000, their percentage metropolitan increased more than every other group during the period. As a result, the range between the highest and lowest percentages metropolitan declined between 1970 and 2000.

Among people who reported being more than one race, a choice available for the first time in Census 2000, a relatively high percentage ( 88 percent) lived in metropolitan areas. They were slightly less likely than Asians and Pacific Islanders and Hispanics, but more likely than Blacks, Whites, and American Indians and Alaska Natives to live in a metropolitan area.

Figure 3-17.

## Percent Metropolitan by Race and Hispanic Origin: 1960 to 2000

Note: Data on Hispanic origin have been available on a 100-percent basis since 1980 only, and data on the population of Two or more races are available from Census 2000 only.
Source: U.S. Census Bureau, decennial census of population, 1960 to 2000.

# The White, Black, and American Indian and Alaska Native populations all aged over the century. 

As Figure 3-18 shows, every race group's age structure changed considerably from 1900 to 2000. The White and Black populations followed a somewhat similar pattern while the changes among the American Indian and Alaska Native population and the Asian and Pacific Islander population were more distinct. While fertility and mortality trends have influenced the age structure changes in all these populations, immigration trends have also been a major factor underlying changes in the age structure of the Asian and Pacific Islander population.

In 1900, the White, Black, and American Indian and Alaska Native populations were all relatively young, which can be seen by the pyramid shape of their age structures. The under 5 age group was the largest for all three races (see Appendix Table 11). On the other hand, the Asian and Pacific Islander population in 1900 consisted largely of working-age men, as a result of the heavy influx of Chinese and Japanese workers to the United States during the late 19th century. The largest 5-year age group was 35-to-39 year olds, who made up 15 percent of the Asian and Pacific Islander population. The absence of women in the population pyramid reflects the effects of various exclusionary immigration policies. As a result of the unique immigration patterns of the Asian and Pacific Islander population, its age pyramid in 1900 differed sharply from that of the other races and this marked difference continued for decades.

From 1900 to 1950, the White and Black populations became older as fertility declined, but somewhat large proportions of their populations were still under age 10. The largest 5 -year age group for both Blacks and Whites in 1950 was children under age 5. This reflects
the fertility during the start of the post World War II baby boom.

The American Indian and Alaska Native population remained a very young population in 1950, and the base of its age pyramid had not narrowed since 1900 as it did in the White and Black populations. This was due to the relatively high fertility of the American Indian and Alaska Native population. Graphically, the age structure generally remained in the classic pyramid shape of five decades earlier. The under 5 age group among American Indians and Alaska Natives was still proportionally larger (15 percent of the total) than the rest of the other 5 -year age groups.

By 2000, the age structures of the White, Black, and American Indian and Alaska Native populations had taken on a more rectangular shape, characteristic of older populations. While all three groups had older populations, the White population was the oldest. In 2000, 7.0 percent of the White population was 75 years or older compared with only 2.1 percent of the American Indian and Alaska Native population and 3.5 percent of the Black population.

The age structure of the Asian and Pacific Islander population changed significantly during both halves of the century. From 1900 to 1950, it became much less unbalanced among the different age groups and also between the sexes. By 2000, the age structure of the Asian and Pacific Islander population more closely resembled the age structures of the White, Black, and American Indian and Alaska Native populations, with a more balanced sex ratio. However, the influence of international migration remained, as evidenced by the relatively high proportion in the young adult age groups.

Figure 3-18.
Age and Sex Distribution of the Total Population by Race:
1900, 1950, and 2000

Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

## In 1980 and 2000, Hispanics were much younger than non-Hispanics.

The age and sex distributions for the Hispanic and nonHispanic populations for 1980 and 2000 are shown by the population pyramids in Figure 3-19. The shapes of the pyramids reveal that Hispanics were much younger than non-Hispanics in 1980 and 2000, although both populations "aged" over the 20-year period.

The age and sex distributions of the Hispanic population in 1980 and 2000 show large proportions at young ages and progressively smaller proportions at older ages, indicating a relatively young population. The wider base of the pyramid reflects relatively high Hispanic fertility. Comparatively, the age and sex pyramid of the non-Hispanic population has a much more rectangular shape, indicative of an older population. The base of the non-Hispanic pyramid is narrower, and the proportion of the population in the older age groups is much higher.

In 1980, children under age 5 represented the largest 5 -year age group ( 11 percent) of the Hispanic population, compared with non-Hispanics, who had only 7 percent of their population under age 5 . In contrast to Hispanics, 20-to-24-year olds represented the largest 5-year age group for the non-Hispanic population in 1980 (see Appendix Table 11).

Two decades later, the Hispanic population had grown older, but remained relatively young. In 2000, the largest 5 -year age group in the Hispanic population was still children under age 5. Among non-Hispanics, the largest 5-year age group in 2000 had shifted to the 40-to-44-year olds, reflecting the aging of the group
born during the peak years of the baby boom (1956 to 1960) over the period 1980 to 2000.

The Hispanic age and sex structure maintained a "bulge" around the broad age range of 15 to 29 years in both 1980 and 2000. While the individual 5 -year age groups within that range did not exceed the proportion of the population in the under 5 age group, together they accounted for nearly one-third of the Hispanic population (31 percent). This bulge resulted primarily from the continued migration of Hispanics to the United States.

For non-Hispanics, the bulge in the 1980 age distribution was also concentrated around the younger age groups, extending roughly from the ages of 15 to 34 years. However, the bulge in the non-Hispanic population in these ages coincides with the presence of the baby-boom generation (roughly ages 16 to 34 in 1980). Unlike the Hispanic age distribution, the bulge in the non-Hispanic population shifted to the age range 35 -to- 54 years by 2000, again reflecting the aging of the baby-boom generation.

The youthfulness of the Hispanic population compared with the non-Hispanic population is also apparent from the proportions of their populations at older ages. While the age distributions of both populations become progressively smaller with age, non-Hispanics had much larger proportions in older age groups than Hispanics. About 5 percent of the Hispanic population was 65 years and over in both 1980 and 2000, whereas people age 65 and over represented 12 percent of non-Hispanics in 1980 and 14 percent in 2000.

Figure 3-19.
Age and Sex Distribution of the Total Population by Hispanic Origin: 1980 and 2000

Source: U.S. Census Bureau, decennial census of population, 1980 and 2000.

## The Black and the American Indian and Alaska Native populations were younger than the White and the Asian and Pacific Islander populations during the entire century.

The trends in median age by race and Hispanic origin over the course of the century reveal some similarities and some marked differences (see Figure 3-20). For example, the White and the Black populations followed similar patterns of change, with increasing median ages every decade during the first half of the century, declining median age in the 1950s and 1960s, and increasing median ages throughout the remainder of the century.

In contrast, the American Indian and Alaska Native and the Asian and Pacific Islander populations followed quite different trends. From 1900 and for most of the century, the median age for American Indians and Alaska Natives changed little, and more than half of this population was under 21 years old (see Appendix Table 11). Asians and Pacific Islanders, on the other hand, had their highest median age at the outset of the century, and it generally declined until 1980. The
high median ages at the beginning of the century are a by-product of predominantly adult male migration.

Apart from the general trends of each group, there have been fairly consistent differences in the relative levels of median ages across race and Hispanic origin. Both Blacks and American Indians and Alaska Natives had younger median ages throughout the century than did other races. Hispanic origin data, first collected on a 100-percent basis in 1980, show that Hispanics also had a young median age. Furthermore, Census 2000 showed that people who reported more than one race are another very young population group. By comparison, the White and the Asian and Pacific Islander populations consistently had higher median ages. Between the race and Hispanic-origin groups, the White non-Hispanic population has had the "oldest" median age, increasing from 31.7 in 1980 to 38.6 in 2000.

Figure 3-20.
Median Age by Race and Hispanic Origin: 1900 to 2000

Note: Data on Hispanic origin have been available on a 100-percent basis since 1980 only, and data on the population of Two or more races are available from Census 2000 only.
Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## Younger age groups had the highest percentage Minority, and older age groups had the lowest.

The rapidly increasing diversity of the U.S. population in the last two decades of the 20th century is indicated by the trend in the age distribution of the aggregate Minority population (see Figure 3-21). ${ }^{46}$ Each broad age group increased in a consistent pattern over the last 20 years of the century.

Figure 3-21 demonstrates that younger age groups have had a higher percentage Minority than older age groups. In 1980, the percentage Minority ranged from 12 percent for the population age 65 and over to 25 percent for people under age 25. By 2000, the percentage Minority ranged from 16 percent for the population age 65 and over to 39 percent for people under age 25.

[^44]For every age group, the percentage-point increase in the 1990s for the Minority population exceeded the 1980s increase. In addition to an overall higher percentage Minority, younger age groups experienced greater percentage-point gains than older age groups in both the 1980s and the 1990s. As a result, the difference between the youngest and the oldest age groups in their percentage of Minority population widened over the 20-year period.

The trends in the percentage Minority for most age groups reflect the relatively high levels of international migration of Asians and Hispanics in recent decades. Since immigration is a less significant factor for the population age 65 years and over, the increase in the percentage Minority for this age group has been less pronounced.

Figure 3-21.
Percent Minority by Broad Age Group: 1980 to 2000

Source: U.S. Census Bureau, decennial census of population, 1980 to 2000.

# American Indians and Alaska Natives had the highest percentage under age 15 and Blacks the second highest, for most of the 20th century. 

During the 20th century, race groups in the United States had varying rates of fertility, the principal factor determining the proportion of young people in a population. Even so, nearly every race group experienced a general decline in their young populations.

The proportion under age 15 was lower in 1940 than in 1900 for every race group, with the exception of the Asian and Pacific Islander population (see Figure 3-22). Asians and Pacific Islanders experienced a large increase in their young population due to a combination of factors, including the increased immigration of families and their natural increase.

The only period of increase in the under age 15 population for every race group occurred from 1940 to 1960. This period coincides with the majority of the baby-boom years (1946 to 1964). However, from the 1960s onward, the proportion of young people in each race group's population continued to decline as fertility rates declined. Hispanics experienced a slight increase in the proportion under age 15 years during the 1990s.

The Black and the American Indian and Alaska Native populations had much higher proportions of people under 15 years of age compared with the White and the Asian and Pacific Islander populations. The American Indian and Alaska Native population had the highest percentage under age 15 for most of the 20th century, and in 1960 had a higher proportion ( 42 percent) than any race or ethnic group during the entire century (see Appendix Table 11).

In 1980, when data first became available for the Hispanic population at the 100-percent level, Hispanics had the highest percentage under age 15 (32 percent) among the groups considered, although just slightly higher than the American Indian and Alaska Native population. Relatively high fertility of the Hispanic population mainly accounts for this high proportion. On the other hand, White non-Hispanics had the lowest percentage under age 15 from 1980 to 2000. In 2000, the Two or more races population (available in Census 2000 for the first time) had the highest proportion of people under age 15 (36 percent).

Figure 3-22.
Percent Under Age 15 by Race and Hispanic Origin: 1900 to 2000

Note: Data on Hispanic origin have been available on a 100-percent basis since 1980 only, and data on the population of Two or more races are available from Census 2000 only.
Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

# Since 1930, the White (and since 1980 the White non-Hispanic) population has had the highest percentage age 65 years and over. 

The proportion of the population age 65 years and over was higher in 2000 than in 1900 for every race (see Figure 3-23), but different trends occurred among the groups. For the Black and White populations, the proportion elderly grew steadily, in contrast to the fluctuation in the proportion 65 years and over for the Asian and Pacific Islander population. The proportion elderly for American Indians and Alaska Natives fluctuated slightly, but remained relatively stable over the course of the century.

The White population experienced the largest increase in its proportion elderly, from 4 percent in 1900 to 14 percent in 2000. Conversely, the American Indian and Alaska Native population experienced the least change in its proportion elderly, varying from 4.6 percent in 1900 to 5.8 percent in 1990 (see Appendix Table 11).

The American Indian and Alaska Native population had the highest proportion elderly from 1900 to 1920, but then had one of the lowest proportions elderly by the end of the century. By 1930, the proportion of the White population that was 65 years and over had surpassed that of the American Indian and Alaska Native population. Since then, the White, and since 1980, the White
non-Hispanic, populations have had, by far, the highest percentage elderly. In 2000, the White non-Hispanic population had the century's highest proportion age 65 years and over of any race or ethnic group (15 percent). This results primarily from the sustained lower fertility levels of this population group.

Over the decades, the group with the lowest proportion of elderly shifted across race and ethnic groups. Asians and Pacific Islanders had the lowest proportion elderly from 1900 to 1940 (and the lowest of the century1.5 percent in 1900), followed by American Indians and Alaska Natives from 1950 to 1970. Since 1980, when data on the Hispanic population were first collected on a 100-percent basis, Hispanics have had the lowest proportion of elderly in each census. Relatively high levels of fertility combined with large-scale immigration of young adults have kept the proportion of elderly low among Hispanics. Census 2000, the first census to allow individuals to report themselves as more than one race, found that the Two or more races population also had a low proportion age 65 and over ( 5.0 percent), comparable to that of the Hispanic population (4.9 percent).

Figure 3-23.
Percent Age 65 and Over by Race and Hispanic Origin: 1900 to 2000

Note: Data on Hispanic origin have been available on a 100-percent basis since 1980 only, and data on the population of Two or more races are available from Census 2000 only. Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

## Black females outnumbered Black males in every decade of the century.

The sex ratio trends of the Black and the White populations have been similar during the century, while the Asian and Pacific Islander population and the American Indian and Alaska Native population have followed two distinct patterns (see Figure 3-24).

The sex ratios of the White and the Black populations increased early in the century, steadily declined to 1980, then increased to 2000. The arrival of relatively more male immigrants at the beginning of the century contributed to the initial sex ratio increase for Whites. Greater improvement in female than male mortality rates generally explains the declining sex ratios up to 1980 for the White and Black populations, while greater improvement in male than female mortality rates in part explains the 1980 to 2000 increase.

The sex ratio for Asians and Pacific Islanders varied much more than for other race groups. In 1900, Asian and Pacific Islanders had the highest sex ratio $(1,974)$ of the century. This extreme excess of males originated because Asian and Pacific Islander immigrants in the late 19th century were almost exclusively men. As late as 1950, Asians and Pacific Islanders had a sex ratio of 145 (see Appendix Table 16). The sex ratio declined as family immigration and fertility among the immigrants increased the representation of women within the Asian and Pacific Islander population.

The sex ratio trend for the American Indian and Alaska Native population also followed a unique path. In
general, the sex ratio rose from 1900 to 1950, declined to 1970, and increased slightly for the remainder of the century. Interpreting the factors contributing to this trend is problematic, as documentation of changes in the American Indian and Alaska Native population have been affected by changes in census procedures and changes in racial affiliation. ${ }^{47}$

Between the race and Hispanic-origin groups, Blacks had the lowest sex ratio throughout the century. Black females outnumbered Black males every decade, and the Black population had the century's lowest sex ratio (89.6) in 1980. Differences in the census coverage of Black males relative to Black females contributed to overall lower sex ratios for the Black population, as did a comparatively lower sex ratio at birth.

Asians and Pacific Islanders had the highest sex ratio of the race and ethnic groups from 1900 to 1970. Hispanics maintained the highest sex ratio of these groups from 1980 to 2000.

At the end of the century, the male population exceeded the female population among Hispanics and (slightly) for the Two or more races population. For all other race and ethnic groups, the female population outnumbered the male population.

[^45]Figure 3-24.
Sex Ratio by Race and Hispanic Origin: 1900 to 2000

Note: Data on Hispanic origin have been available on a 100-percent basis since 1980 only, and data on the population of Two or more races are available from Census 2000 only. Data for the Asian and Pacific Islander population by sex are available prior to 1960 but the sex ratios are not shown since the values far exceed the highest level shown in Figure 3-24. The sex ratios for the Asian and Pacific Islander population declined from 1,974 in 1900 to 145 in 1950.

Chapter 4
HOUSING

## Chapter Highlights <br> HOUSING

## National Trends

From 1940 to 2000, the number of housing units in the United States more than tripled-from 37.3 million to 115.9 million.

From 1940 to 2000, the largest housing unit increase ( 19.7 million) occurred in the 1970s, and the smallest increase ( 8.7 million) took place in the 1940s.

The number of vacant housing units increased in every decade from 1940 to 2000, except for the 1960 s, when they declined by 73,000 . The lowest housing vacancy rate ( 6.6 percent) occurred in 1940, and the highest vacancy rate ( 10.1 percent) in 1990.

Prior to 1950, over half of all occupied housing units were rented. By 1950, homeownership became more prevalent than renting. The homeownership rate continued to increase until 1980, decreased slightly in the 1980 s, and then increased in the 1990s, reaching the highest level of the century (66 percent) in Census 2000.

From 1960 to 2000, nonmetropolitan areas had higher homeownership rates than metropolitan areas. Within metropolitan areas, the homeownership rate was much higher in the suburbs than in central cities.

From 1960 to 2000, householders age 65 years and over were more likely to own their homes than householders under age 65.

At the end of the 20th century, householders who were Black, Hispanic, or of two or more races were more likely to rent than own their homes.

From 1940 to 2000, householders living alone were less likely to own their homes than householders living with other people.

## Regional Trends

Every region experienced an increase in vacancy rates during the 1950s, 1970s, and 1980s and a decrease in vacancy rates during the 1960s and the 1990s.

From 1940 to 1960, the West had the highest vacancy rate, then from 1970 to 2000, the South had the highest vacancy rate.

The 1930s was the only decade when the proportion of owner-occupied housing units declined in every region. The largest increase in homeownership rates for each region then occurred in the following decade, the 1940s, as the economy recovered from the Depression and experienced post-World War II prosperity.

Each region's highest homeownership rate of the century was recorded in 2000.

The Midwest had the highest homeownership rate for every decade of the century, except in 1910, when the West ranked first.

## State Trends

Ohio and Illinois ranked among the ten states with the lowest vacancy rates in every census from 1940 to 2000.

Maine, Montana, New Hampshire, and Vermont all ranked among the ten states with the highest vacancy rates every census from 1940 to 2000.

South Carolina's homeownership rate experienced the largest percentage point increase (42 percentage points) during the century, from 31 percent in 1900 to 72 percent in 2000. North Dakota experienced the largest percentage point drop (14 percentage points) in its homeownership rate, from 81 percent in 1900 to 67 percent in 2000.

Michigan and Minnesota were the only two states to be among the ten states with the highest homeownership rates for every census. States with consistently low homeownership rates included Alaska, Hawaii, Massachusetts, New York, and Rhode Island.

## Chapter 4 <br> HOUSING

Prior to 1940, the population census collected limited information on the number of occupied housing units in the United States. More detailed information on the characteristics of housing units became available when the first census of housing was conducted in 1940. Information on housing tenure (owner occupied or renter occupied) has been collected on a 100percent basis since 1900 and information on occupancy status (occupied or vacant) since 1940. Many other characteristics of housing units were collected in Census 2000, but only on a sample-basis.

In the 20th century, a basic American dream of owning a home became a reality for the majority of U.S. households. In the censuses of 1900 to 1940, most Americans reported renting their homes. By 1950, most Americans owned their homes, and by 2000, homeownership in the United States had reached its highest level (66 percent) ever. Economic prosperity, changes in the mortgage financing system, and corresponding increases in the proportion of households that could afford to buy a home propelled these 20th century trends.

The number of housing units in the United States tripled from 37.3 million in 1940 to 115.9 million in 2000. During the same period, the number of vacant housing units increased from 2.5 million to 10.4 million, representing 9 percent of all U.S. housing units in 2000. Vacancy rates both nationally and in each region fluctuated over the years. From 1970 to 2000, the South had the highest proportion of vacant housing units. Most state vacancy rates were higher in 2000 than in 1940, and the 11 states whose vacancy rates decreased were in either the Northeast or the West. Only Ohio and Illinois consistently ranked among the ten states with the lowest vacancy rates from 1940 to 2000, while Maine, Montana, New Hampshire, and Vermont all consistently ranked
among the ten states with the highest vacancy rates during this period. These high vacancy rate states have high proportions of "seasonal vacants."

While the homeownership rate in the United States reached its highest level ever in Census 2000, important geographic differences and differences by the characteristics of the householder remained. Regionally, the Midwest (except for 1910) had the highest rate of homeownership throughout the century. By the end of the century, homeowners represented the majority of householders in the 50 states. (In the District of Columbia, a state equivalent for statistical purposes, renters continued to outnumber homeowners.) Census data reveal that from 1960 to 2000, central city householders had lower levels of homeownership than suburban householders and nonmetropolitan householders throughout the period. Considering householder characteristics, older householders, White and White non-Hispanic householders, and householders living with at least one other person were more likely to be homeowners than younger householders, Hispanic or race-other-than-White householders, or people living alone, respectively.

The graphics and text in this chapter depict the trends in the number and proportional distribution of total, occupied, and vacant housing units and in the numbers and proportions of owner-occupied and renteroccupied housing units. Trends are shown for different periods of time depending on the availability of data. Housing unit and homeownership trends are examined for the United States, regions, and states (and by metropolitan status for homeownership). Additionally, the chapter discusses homeownership trends by the age, race, and Hispanic origin of the householder and by the size of the household. Appendix Table 12 provides detailed data by occupancy and tenure.

## Between 1940 and 2000, about 90 percent of all housing units were occupied.

In 1940, when the U.S. Census Bureau conducted the first census of housing, there were 37.3 million housing units (see Figure 4-1). ${ }^{48}$ By 2000, the number of housing units had more than tripled to 115.9 million. The largest numerical census-to-census increase in housing units ( 19.7 million) and the highest percentage increase (29 percent) occurred from 1970 to 1980. While the smallest numerical increase in housing units ( 8.7 million) took place in the 1940s, the lowest percentage increase (13 percent) occurred in the 1990s.

As Figure 4-1 shows, housing units are classified as either occupied or vacant. From 1940 to 2000, the number of occupied housing units increased every decade. In 1940, there were 34.9 million occupied housing units. By 2000, the number of occupied housing units had tripled to 105.5 million. As was true for total housing units, both the largest numerical and percentage increases in occupied units occurred in the 1970s ( 16.9 million and 27 percent, respectively). The smallest numerical increase in occupied housing units ( 8.0 million) occurred in the 1940s and the lowest percentage increase (14 percent) in the 1980s.

Vacant housing units increased every decade except for the 1960s, when they declined by 1.4 percent, or

[^46]by 73,000 units (see Appendix Table 12). In 1940, there were 2.5 million vacant housing units. By 2000, there were 10.4 million vacant housing units. The largest increase in vacant housing units ( 2.8 million) coincided with the largest increase in occupied housing units from 1970 to 1980, while the highest percentage increase (68 percent) occurred in the 1950s.

From 1940 to 2000, the proportion of all housing units that were occupied remained fairly stable (see Figure 4-2). Vacant housing units exist for a number of reasons, such as local economic conditions, seasonal housing units, or the result of people moving from one residence to another. ${ }^{49}$

In 1940, only 6.6 percent of all housing units were vacant, the lowest vacancy rate from 1940 to 2000. Between 1940 and 1960, the proportion of vacant housing units increased slightly, while from 1960 onward the proportion of vacant housing units fluctuated. The highest vacancy rate was in 1990, when 10.1 percent of all housing units in the United States were vacant.

(Percent)
Vacant housing units
Occupied housing units

Source: U.S. Census Bureau, decennial census of housing, 1940 to 2000.

## From 1970 to 2000, the South had the highest housing vacancy rate.

The regions generally followed similar patterns in the changes in their proportion of vacant housing units from 1940 to 2000 (see Figure 4-3). Every region experienced an increase in vacancy rates during the 1950s, 1970s, and 1980s and a decrease in vacancy rates during the 1960s and the 1990s.

The Northeast, the Midwest, and the South had their highest vacancy rate in 1990 ( 9.3 percent, 8.9 percent, and 11.8 percent, respectively). The lowest vacancy rate in the Midwest and the South occurred in 1940 ( 5.5 percent for both), and the Northeast's lowest vacancy rate occurred in 1950 ( 6.8 percent). The West differed from the other regions, as its highest vacancy rate was in 1960 ( 9.8 percent) and was followed by its lowest vacancy rate in 1970 ( 7.1 percent).

The regions experienced different ranges in their vacancy rates over the 1940 to 2000 period. The Northeast experienced the narrowest range (2.5 percentage points), and the South experienced the widest gap (6.3 percentage points).

From 1940 to 1960, the West had the highest vacancy rate among the regions. From 1970 to 2000, the South recorded the highest vacancy rates in the country, including the highest vacancy rate of any region during the period from 1940 to 2000 ( 11.8 percent in 1990). The Midwest or the Northeast had the lowest vacancy rate in every census from 1940 to 1990. The West had the lowest vacancy rate ( 7.9 percent) in 2000, becoming the only region to have had both the lowest and the highest (from 1940 to 1960) vacancy rates during the 1940 to 2000 period.

The difference in the vacancy rates between the region with the highest rate and the region with the lowest rate varied. The largest differential ( 3.5 percentage points) occurred in 1940, when the West had a vacancy rate of 8.9 percent and the Midwest a vacancy rate of 5.5 percent. By 1960, the difference in vacancy rates decreased to 1.4 percentage points, the smallest difference of the period. The difference increased to 2.9 percentage points in 1990 and then decreased to 2.4 percentage points in 2000.

Figure 4-3.
Vacancy Rate by Region: 1940 to 2000

Source: U.S. Census Bureau, decennial census of housing, 1940 to 2000.

# From 1940 through 2000, Maine, New Hampshire, Vermont, and Montana ranked among the ten states with the highest vacancy rates. 

Most states had higher vacancy rates in 2000 than they did in 1940, but only 11 states in the Northeast or the West had lower rates: California, Colorado, Connecticut, Massachusetts, Nevada, New Hampshire, New Jersey, New York, Oregon, Rhode Island, and Washington.

From 1940 to 2000, an increasing number of states had a housing vacancy rate of 10 percent or more (see Figure 4-4). In 1940, eight states (Arizona, Colorado, Florida, Maine, New Hampshire, New Jersey, New Mexico, and Vermont) had vacancy rates of at least 10 percent. In some cases, particularly in Florida and Maine, higher vacancy rates result from a relatively high proportion of housing units classified as "Vacant for seasonal, recreational, and occasional use," also known as "vacation" homes.

By 2000, the number of states with a vacancy rate of 10 percent or more tripled to 24 . Four states (Maine, New Hampshire, New Mexico, and Vermont) maintained a vacancy rate of 10 percent or higher from 1940 through 2000 (see Appendix Table 12).

Ohio and Illinois were the only states to be among the ten states with the lowest vacancy rates every decade from 1940 to 2000. The vacancy rate remained below 7 percent for the entire period in Illinois, and from 1940 to 1990 in Ohio.

The lowest vacancy rate during the period from 1940 to 2000 occurred in the District of Columbia in 1950, when only 2.4 percent of its housing units were vacant. Among the 50 states, West Virginia had the lowest vacancy rate during the period: 3.2 percent in 1940. However, by 2000, the vacancy rate in West Virginia had risen to 13 percent, a rate well above the national average of 9 percent.

Maine had the highest vacancy rate from 1940 to 2000, at 24 percent in 1970. Even at its lowest level of vacancy in 1940, 16 percent of the housing units in Maine were vacant. Maine, Montana, New Hampshire, and Vermont all ranked among the ten states with the highest vacancy rates every decade from 1940 to 2000.

The six states which were below the national vacancy rate every decade from 1940 to 2000 were Illinois, Indiana, Iowa, Ohio, Tennessee, and Virginia.

From 1940 to 2000, more states (25) experienced their lowest vacancy rate in 1940 than in any other census year. On the other hand, more states (22, including the District of Columbia) experienced their highest vacancy rate in 1990 than in any other census year.

Source: U.S. Census Bureau, decennial census of housing, 1940 and 2000.

## Since 1950, more than half of all occupied housing units have been owner occupied.

Occupied housing units are classified as either owned or rented. Renter-occupied housing units outnumbered owner-occupied housing units from 1900 to 1940 (see Figure 4-5). In 1900, there were 8.2 million renter-occupied housing units and 7.2 million owneroccupied housing units. Owner-occupied units increased by only 1.2 million from 1930 to 1940, while renter-occupied units increased by 4.3 million.

As the U.S. economy improved during the 1940s, so did the level of homeownership. From 1940 to 1950, owner-occupied units increased by 8.4 million while renter-occupied units decreased by about 400,000, the only decrease in either owner- or renter-occupied housing units to take place during the century.

From 1900 to 1950, the number of owner-occupied housing units tripled to 23.6 million. The number of renter-occupied units more than doubled to 19.3 million. By 1950, owner-occupied units outnumbered renter-occupied units and continued to do so for the remainder of the century.

From 1950 to 2000, the increase in owner-occupied units far outpaced the growth of renter-occupied units. Owner-occupied units grew by 46.3 million, to a total of 69.8 million in 2000, while renter-occupied units increased by only 16.4 million, to a total of 35.7 million in 2000.

In 1900, 47 percent of housing units were owner occupied (see Figure 4-6), a proportion that remained fairly stable until the 1930s, when the depression lowered homeownership rates. By 1940, only 44 percent of housing units were owner occupied, the lowest proportion of owners during the entire century.

By 1950, more than half of all occupied housing units were owned. Homeownership rates had surpassed rental rates and continued to increase until 1980, when 64 percent of housing units were owner occupied. The homeownership rate decreased slightly during the 1980s, but increased during the 1990s to reach the highest homeownership rate of the century in 2000 at 66 percent.

Figure 4-5.
Occupied Housing Units by Tenure: 1900 to 2000

## For every decade, except the 1910s, the Midwest had the highest homeownership rate.

Every region followed a relatively similar pattern in homeownership rates over the century and had a higher homeownership rate in 2000 than in 1900 (see Figure 4-7). Homeownership rates among the regions ranged from 37 percent in the Northeast in 1910 to 70 percent in the Midwest in 2000.

The period from 1930 to 1940 was the only decade in which the proportion of owner-occupied housing units declined in every region. Conversely, the largest per-centage-point increase in homeownership rates for every region took place during the following decade, from 1940 to 1950, as the U.S. economy rebounded and home building expanded after World War II.

Homeownership rates continued to increase during the 1950s. By the 1960 census, the rate of homeownership was 50 percent or higher in every region for the first time, and it remained above 50 percent through the end of the century.

In 1940, the Midwest, the South, and the West recorded their lowest homeownership rates of any decennial census during the century, while the Northeast experienced
its lowest rate in 1910. Each region's highest homeownership rate of the century occurred in 2000.

Among the regions, the Midwest had the highest homeownership rate for every decade of the century, except in 1910, when the West ranked first. More than half of all housing units in the Midwest and in the West were owner occupied at every census, except in 1940, when the homeownership rate declined to 49 percent. During the first half of the century, the West ranked behind the Midwest in terms of homeownership but was replaced by the South from 1960 to 2000. The Northeast had the lowest homeownership rate for most of the century, except for the South in 1930 and the West in 1990 and 2000.

Since 1910, the gap between the region with the highest homeownership rate and the region with the lowest homeownership rate narrowed each decade, except in the 1940s. The widest differential was 18.7 percentage points in 1910 ( 55 percent in the West and 37 percent in the Northeast). The smallest differential was 8.7 percentage points in 2000 ( 70 percent in the Midwest and 61 percent in the West).

Figure 4-7.
Percent Owner-Occupied Housing Units by Region: 1900 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900 to 1930, and decennial census of housing, 1940 to 2000.

# Michigan and Minnesota were the only states to rank among the ten states with the highest homeownership rates throughout the century. 

Overall, homeownership rates among the states and the District of Columbia were higher in 2000 than they were in 1900 (see Figure 4-8). Idaho, Nevada, North Dakota, and South Dakota were the only states with lower homeownership rates in 2000 than in 1900. The lowest and the highest homeownership rates of the century occurred in 1900 ( 24 percent in the District of Columbia and 81 percent in North Dakota).

In 1900, 26 states had homeownership rates of 50 percent or higher. Of those 26 , only 3 states, Idaho, South Dakota, and North Dakota, had homeownership rates of 70 percent or higher. By 2000, all 50 states had a homeownership rate of 50 percent or higher and the number of states with a homeownership rate of 70 percent or more had increased to 17 .

Several states experienced significant increases or decreases in their homeownership rates from 1900 to 2000. South Carolina experienced the largest percent-age-point increase, from 31 percent in 1900 to 72 percent in 2000 (an increase of 42 percentage points). Other states that experienced increases of 30 percentage points or more were Alabama, Delaware, Georgia, Louisiana, Mississippi, New Jersey, and Rhode Island. North Dakota experienced the largest percentage-point drop (14 percentage points) in its homeownership rate, from 81 percent in 1900 to 67 percent in 2000.

Several states had consistently high ( 50 percent or more) homeownership rates over the century (see Appendix Table 12). These states are concentrated in the upper

Midwest and the West. For example, Michigan and Minnesota were the only states that ranked among the ten states with the highest homeownership rates at every census. Idaho, Maine, and Utah were also among the top ten, with the exception of a decade or two. Utah was the only state in which the homeownership rate never dropped below 60 percent.

On the other hand, states with consistently lower homeownership rates included Alaska, Hawaii, Massachusetts, New York, and Rhode Island. In 1980, New York was the only state with more renters than homeowners, but by 1990, it reached a homeownership rate exceeding 50 percent. The District of Columbia, a state equivalent for statistical purposes, had the lowest homeownership rate for every census but one (Georgia was lowest in 1930) and never reached a homeownership rate of 50 percent. In 2000, it reached its highest homeownership rate at 41 percent.

The ranking of the rate of homeownership by state changed significantly during the century. Comparing rankings in 1900 with those in 2000, Alabama, Delaware, Mississippi, and South Carolina experienced the largest increases, led by South Carolina's jump from 47th to 9th in 2000. Nevada, North Dakota, Oregon, and South Dakota experienced the largest decreases in their rank of homeownership, led by Nevada's drop from 6th in 1900 to 46th in 2000.

## Residents in central cities have been much less likely to own their homes.

From 1960 to 2000, nonmetropolitan ${ }^{50}$ areas had higher homeownership rates than metropolitan areas (see Figure 4-9). Homeownership rates in nonmetropolitan areas ranged from 67 percent in 1960 to 74 percent in 2000. Homeownership rates in metropolitan areas ranged from 59 percent in 1960 to 64 percent in 2000. Even at its highest point, the homeownership rate in metropolitan areas was still below the lowest homeownership rate in nonmetropolitan areas (see Appendix Table 16).

Homeownership rates were higher in 2000 than in 1960 for both metropolitan and nonmetropolitan areas. The homeownership rate increased every decade from 1960 to 2000 for metropolitan areas, while the rate in nonmetropolitan areas increased

[^48]from 1960 to 1980 , declined during the 1980 s, and then increased again during the 1990s.

Within metropolitan areas, the homeownership rate in the suburbs was much higher than in central cities. During the period 1960 to 2000, the homeownership rate ranged from 70 percent to 73 percent in the suburbs but from 47 percent to 51 percent in central cities. In 1960, the homeownership rate in the suburbs was higher than in nonmetropolitan areas, but from 1970 onward, nonmetropolitan areas have had a higher homeownership rate than either suburban areas or central cities.

Less than half of occupied housing units in central cities were owner occupied from 1960 to 1990. Owner-occupied units exceeded renter-occupied units in central cities for the first time in Census 2000.

Figure 4-9.
Percent Owner-Occupied Housing Units by Metropolitan Status: 1960 to 2000

# Householders age 65 years and over were more likely to own a home than householders under age 65. 

As people age, they are more likely to have characteristics that make it easier to own a home, such as being married and having a higher income. In general, homeownership rates increase as age increases, peaking at 65 -to- 74 years of age and declining with age thereafter. ${ }^{51}$ As Figure 4-10 shows, from 1960 to 2000, householders age 65 years and over were more likely to own their homes than householders under age 65.

The homeownership rate among householders age 65 and over declined between 1960 and 1970; among householders under age 65 it declined between 1980 and 1990, but both groups attained their highest homeownership rates in 2000, 78 percent and 63 percent, respectively.

[^49]In addition to having higher homeownership rates, elderly ${ }^{52}$ homeowners experienced a larger percentagepoint increase in their homeownership rate from 1960 to 2000 , increasing by 6.2 percentage points, than householders under age 65, who increased by 4.7 percentage points.

The difference between the homeownership rates of householders age 65 and over and householders under age 65 converged to its lowest point in 1970, 5.8 percentage points. From 1970 to 2000, the difference in their homeownership rates steadily widened. The homeownership rate among householders age 65 and over steadily increased. The homeownership rate among householders under age 65 increased during the 1970s, decreased during the 1980s, and then increased again during the 1990s. In 2000, the differential between their homeownership rates was the largest in the 1960 to 2000 period: 15.1 percentage points.

[^50]Figure 4-10. Homeownership Rate by Age of Householder: 1960 to 2000
(Percent)

[^51]
# In 1980 and 2000, householders who were Black, Hispanic, or of two or more races were more likely to rent than to own their homes. 

Homeownership rates were higher in 2000 than in 1980 for all race groups and for Hispanics, however, there were also distinct differences among these groups (see Figure 4-11).

White non-Hispanic householders had the highest homeownership rates in 1980 and 2000, 68 percent and 72 percent, respectively, and White householders ${ }^{53}$ had only slightly lower rates. The homeownership rates of all other races and of Hispanics were much lower and below the national averages of 1980 and 2000 (64 percent and 66 percent, respectively).

Following White householders, American Indian and Alaska Native householders and Asian and Pacific Islander householders had the next highest homeownership rates, respectively. Their homeownership

[^52]rates were in the 52 percent to 56 percent range in 1980 and 2000.

Blacks and Hispanics had similar homeownership rates in 1980 and 2000, below 50 percent. In 1980, the rate for Blacks was 44 percent and for Hispanics it was 43 percent. In 2000, the homeownership rate for both groups and for householders who reported themselves as more than one race was 46 percent. At the end of the century, householders who were Black, Hispanic, or of two or more races were more likely to rent than to own their homes.

In addition to having the highest homeownership rate, White non-Hispanic householders also had the largest increase in their homeownership rate from 1980 to 2000 of any race group and Hispanics ( 4.0 percentage points). Asian and Pacific Islander householders had the smallest increase in their homeownership rate (0.7 percentage points).

Figure 4-11.

## People living alone were less likely to own their homes than householders living with other people.

From 1940 to 2000, householders living alone were less likely to own their homes than householders living with other people (see Figure 4-12). In part, this reflects higher mobility rates and the generally more limited economic resources available for one-person households. In addition, some one-person householders may prefer to rent, rather than own, their homes.

The homeownership rate of householders living with other people rose from 44 percent in 1940 to 71 percent in 2000. The homeownership rate for householders living alone ranged from 39 percent in 1940 to 52 percent in 2000, the first time people living alone became more likely to own, rather than rent, their homes. Both groups experienced their lowest homeownership rate in 1940 and their highest homeownership rate in 2000.

Both types of householders experienced one decade of decline in their homeownership rate, during the 1950s for one-person households and the 1980s for householders living with other people. The 1980s was also the decade in which householders living alone experienced the largest increase in their homeownership rate.

From 1940 to 1980, the differential between the homeownership rates of householders living alone and householders living with other people widened. The difference in their homeownership rates increased from 4.6 percentage points in 1940 to 27 percentage points in 1980. From 1980 to 2000, the differential converged.

Chapter 5
HOUSEHOLDS

## Chapter Highlights HOUSEHOLDS

## National Trends

In 1900, the most common household contained seven or more people. From 1940 to 2000, households with two people represented the most common household size.

Average household size declined from 4.60 in 1900 to 2.59 in 2000 , or by 44 percent.

Householders age 45 and over represented the majority of all householders during the period 1950 to 2000.

Between 1950 and 2000, married-couple households declined from more than three-fourths of all households (78 percent) to just over one-half (52 percent) of all households.

The proportional share of one-person households increased more than any other size. In 1950, one-person households represented 1 of every 10 households ( 9.5 percent), but by 2000, they composed 1 of every 4 households (26 percent).

During the period 1960 to 2000, women age 65 and over accounted for 27 percent to 33 percent of oneperson households, but just 5 percent to 8 percent of the total population.

In every census from 1970 to 2000, approximately three-fourths of all female householders age 65 and over lived alone.

The proportion of one-person households maintained by women decreased in each census, 1970 to 2000, although women still constituted the majority (57 percent) of one-person households in 2000.

In 1970, women represented about 1 of every 5 (21 percent) householders in the United States. By 2000, the proportion had grown to more than 1 of every 3 (36 percent) U.S. householders.

For total, married-couple, and other family households, the proportion of female householders among

Black householders exceeded the proportion of female householders among householders of any other race or Hispanics.

In 1960, 3 of every 5 (59 percent) married-couple households included at least one of their own children under age 18. By 1990 (and in 2000), less than half (46 percent) of married-couple households had an own child under age 18.

In 1950, only 1 of every 5 (19 percent) male family households with no wife present had an own child under age 18. By 2000, half ( 50 percent) of all male family households with no wife present had at least one own child under age 18.

## Regional Trends

The West's share of all U.S. households increased during every decade of the century, while the slow growth of households in the Midwest led to this region representing an ever-shrinking share of all households.

By 2000, one-person households represented about one-fourth of all households in each region.

The West had the highest proportion of one-person households for each census from 1940 to 1970. The Northeast had the highest regional proportion from 1980 to 2000.

## State Trends

In 1940, fewer than 20 percent of the households in every state were one-person households. In 1970, only California, the District of Columbia, and New York had at least 20 percent one-person households. By 2000, every state, except Utah, had at least 20 percent one-person households.

Nevada, California, Arizona, and Idaho ranked among the 10 states with the highest percentage of one-person households in 1900 and 1940, but ranked among the 12 states with the lowest percentage of one-person households in 2000.

## Chapter 5 <br> HOUSEHOLDS

The number, size, types, and age, sex, and racial composition of households in the United States markedly changed in the 20th century, particularly in the later decades. Contributing factors included women having fewer children, changes in age at first marriage, increased mobility of the population, affordability of homes, and the overall increase in the racial and ethnic diversity of the U.S. population. A small proportion of the U.S. population lives in group quarters: of the 281.4 million people counted in Census 2000, 273.6 million people lived in households, while 7.8 million people lived in group quarters (such as correctional institutions, nursing homes, and college dormitories).

In 1900, nearly half of the U.S. population lived in households of six or more people. By 2000, more than half of the population lived in households of one, two, or three people. The trends in the number and proportion of householders by age through the last half of the century followed the movement of the baby-boom generation through the census years. Married-couple households fell from over threefourths (78 percent) of all households in 1950 to just over one-half ( 52 percent) of all households in 2000. Other major household types increased, especially one-person households. In the last several decades of the century, the share of one-person households maintained by male householders increased and male householders with no wife present became increasingly likely to have children in their households.

Between 1900 and 2000, overall regional and state trends in the number and distribution of households followed the population trends for these areas. Regionally, the South's and the West's shares of all households increased during the century, while the Northeast's and the Midwest's shares decreased. The proportions of one-person households in all states and regions increased rapidly in the latter part of the century. Notably, in the first half of the century, most western states had much higher proportions of oneperson households than states in other regions, but the ranking of some western states changed markedly during the century. For example, Arizona, California, Idaho, and Nevada ranked among the states with the highest proportions of one-person households in 1900, but the lowest proportions in 2000.

The graphics and text in this chapter depict the trends in the number and proportional distribution of households, sizes of households, and various household types by age, sex, race, and Hispanic origin of the householder. These changes are described for the United States, regions, and states. Age of householder trends focus on broad age groups, and trends in the gender of the householder are discussed for specific family types and by race and Hispanic origin. Detailed data by size and type of household are provided in Appendix Tables 13, 14, and 15.

# The proportion of households with five or more people declined significantly from 1900 to 2000. 

While the total U.S. population increased greatly during the 20th century, the percentage increase in the number of households was even greater, reflecting the trend of higher proportions of people living in smaller households. From 1900 to 2000, the total U.S. population increased from 76 million to 281 million, an increase of 270 percent. By comparison, the total number of U.S. households grew from 16 million in 1900 to 105 million in 2000, an increase of 561 percent (see Figure 5-1 and Appendix Table 13).

Available data on the number of households by size shows that, in absolute numbers, households with one, two, three, or four members increased every decade. Households with five or more people declined in the 1940s, then increased until 1970, declined again in the 1970s and 1980s, and increased again in the 1990s.

Most of the increase in the number of households from 1900 to 2000 ( 89.5 million) occurred among households having one or two members. These categories accounted for nearly two-thirds (65 percent) of the total U.S. increase in the number of households over the 100-year period, while households with 5 or more members represented just 5 percent of the total increase in U.S. households.

In 1900, households with seven or more people represented the most common household size (see Appendix Table 13), reflecting the high fertility in the United States at that time, plus a greater tendency for people to live in extended family households. Two-person households became the most common household size by 1940 and remained so for the rest of the century.

The proportion of households with five or more people declined significantly from 1900 to 2000, from

45 percent to just 11 percent (see Figure 5-2). The share of households with four people, while generally decreasing, remained in the range of 14 percent to 18 percent of all households during the century. Similarly, three-person households remained in the range of 17 percent to 23 percent over the period. Still, the shares of both three-person and four-person households were at their lowest levels at the end of the century.

The shares of both one-person and two-person households greatly increased during the 20th century. In 1900, only 1 of every 5 (20 percent) U.S. households had one or two people. Since 1980, households of one or two people have represented an increasing majority of households in the United States, reaching a combined 58 percent of all households by 2000 . The shares of one-person and two-person households increased nearly every decade, and the share of each of these household sizes was at its highest level at the end of the century. In 2000, about 1 out of every 3 U.S. households ( 33 percent) had two people, and 1 out of every 4 households ( 26 percent) had one person.

The proportion of the household population living in large households has, by definition, always been much larger than the proportion of households that are large. In 1900, the 45 percent of households with five or more people accounted for 66 percent of the household population, and the 30 percent of households with six or more people accounted for 50 percent of the household population. In 2000, the 11 percent of households with five or more people accounted for 24 percent of the household population, and the 4 percent of households with six or more people accounted for 11 percent of the household popuIation (see Appendix Table 13).

# Average household size declined by 2 people per household during the century, from 4.6 people per household in 1900 to 2.6 in 2000. 

The total population of the United States consists of people who live in households and those who live in group quarters. ${ }^{54}$ Average household size is determined by dividing the total household population (or equivalently, the total population excluding the group quarters population) by the total number of households. In the United States, as the proportion of the population living in one-person and two-person households grew, the average number of people per household declined.

Available data for each census year indicates a continuous decline in average household size during the century (see Figure 5-3). Over the first four decades of the 20th century, average household size declined by an average of nearly 1 person, from 4.60 to 3.68 people per household. Then, over the next five decades, average household size again dropped by

[^53]another person, from 3.68 in 1940 to 2.63 in 1990. Average household size declined the least in the 1990s, from just 2.63 to 2.59 people per household. Over the century, average household size declined by 2 people per household, from 4.60 in 1900 to 2.59 in 2000.

Steep declines in average household size occurred in the 1930s and 1940s, in part reflecting the low fertility through the end of World War II. The baby-boom period (1946 to 1964) then had a leveling effect on average household size for the 1950 to 1970 period. The steepest decline in average household size occurred in the 1970s, a period coinciding with the baby-bust period, relatively low levels of immigration, and increasing proportions of people living alone.

As mentioned above, the smallest decline in average household size occurred in the 1990s. Relatively higher immigration levels and the tendency for immigrants to live in larger households may have kept average household size relatively unchanged from 1990 to 2000.

Figure 5-3.
Average Household Size: 1900 and 1930 to 2000
(People per household)

Source: U.S. Census Bureau, decennial census of population, 1900 and 1930 to 2000, and decennial census of housing, 1940.

## From 1900 to 1970, the majority of U.S. households were in the Northeast and Midwest, but since 1980, the majority were in the South and West.

The pattern of change in the total number of households by region mirrors the pattern of change in total population size. The total number of households increased every decade in each region, growing rapidly in the West throughout the century and sharply in the South after 1960.

The Midwest had more households than any other region throughout the period 1900 to 1950 (see Figure 5-4). By 1960, the South had overtaken the Midwest, and the gap between these two regions widened with each decade. The West had far fewer households than any other region until 1990, when it surpassed the Northeast.

Among the regions, the Midwest and the Northeast had the most similar patterns of growth in their total number of households during the 100-year period. In the Midwest, the number of households was 4.4 times larger in 2000 compared with 1900, and in the Northeast it was 4.5 times larger. In contrast, in the South, the number of households in 2000 was 7.8 times larger ( 38.0 million) than in 1900 ( 4.9 million), and in the West, it was 25.3 times larger (see Appendix Table 14).

The growth of households differed by region, altering each region's proportional share of the total number of U.S. households. Rapid growth in the West increased its share of all households during every decade of the century to 21 percent by 2000 (see Figure 5-5). Conversely, the slow growth of households in the Midwest reduced its share of all households from 35 percent in 1900 to 23 percent in 2000 . The proportional share of U.S. households in the Northeast also generally declined during the century, dropping from 29 percent in 1900 to 19 percent by 2000 . The South's share of households followed a more distinctive pattern, declining during the first part of the century, increasing in the 1930 s, followed by a period of stability from 1940 to 1960, and then greatly increasing from 1960 through the end of the century.

The Midwest's proportional share of U.S. households declined the most ( 12 percentage points) during the period 1900 to 2000, from 35 percent in 1900 to 23 percent in 2000 . The Northeast experienced a 9 -per-centage-point loss in share during the century. The West experienced the greatest gain (16 percentage points) in share of all households over the 100-year period.

As noted above, the South's share of U.S. households declined during the first three decades of the century. From 1900 to 1930, its proportional share of all households fell by nearly 2 percentage points. After less than a percentage point increase in the 1930s, followed by a stable period from 1940 to 1960, the South's proportional share of all households rose by 7 percentage points from 1960 to 2000 . Overall, the South had the most stable proportional share of all households, ranging from 29 percent to 36 percent.

Combined, the Northeast and Midwest regions represented the majority of all U.S. households during the period 1900 to 1970 . However, this majority became smaller every decade, declining from 64 percent in 1900 to 52 percent in 1970. By 1980, the South and West represented the majority ( 52 percent) of all U.S. households. By 2000, the South and West together accounted for 57 percent of all households.

Throughout the century, the proportional shares of households remained highly correlated with population size, differing to the extent that the average number of people per household varied by region. For example, at the end of the century, the Northeast, the Midwest, and the South had slightly higher proportional shares of households than population, while the West held a higher proportion of the population than households. This occurs because the West had a relatively larger average household size ( 2.75 people per household) than the Northeast, the Midwest, and the South (2.56, 2.53 , and 2.56 people per household, respectively). ${ }^{55}$

## From 1950 to 2000, slightly more than half of all households were maintained by people age 45 years and over.

The census-to-census growth from 1950 to 2000 in the number of households in categories defined by the age of the householder reflects the changing population by age during this period. The number of householders age 25 to 44 years, 45 to 64 years, and 65 years and over increased every census (see Figure 5-6). Households maintained by a person under age 25 years increased until 1980, declined during the 1980s, then increased slightly in the 1990s. The decline of 1.7 million householders under age 25 in the 1980s coincides with a large decline ( 5.7 million people) in the population age 15 to 24 years, as the baby-boom generation moved out of this age group during the decade.

As the baby-boom cohort became householders and aged, it greatly affected the number of householders in particular age groups. For example, the relatively large increases in the number of households maintained by people under age 25 in the 1960s and 1970s, by people age 25 to 44 in the 1970s and 1980s, and by people age 45 to 64 in the 1990s all occurred as the baby-boom cohort moved into these age ranges during these decades.

The maximum increase in the number of householders in the second half of the 20th century occurred in the 1970s for the total number of households and for every broad age group, except householders age 45 to 64 years, who increased the most in the 1990s. The decade with the minimum census-to-census change in the number of households varied by age group. During the 50-year period, the only decline in the
number of householders among the age groups considered occurred in the 1980s for householders under age 25.

Each of the four broad age groups had a decade in the period 1950 to 2000 when it was the fastest-growing group in terms of percentage change in the number of households. Three of the four groups (all except householders age 65 and over) also had at least one decade when it was the slowest-growing group. Householders age 25 to 44 years most often (in the 1950s, 1960s, and 1990s) grew by the least percentage.

The shares that each age group represented of the total number of households varied over the decades (see Figure 5-7). These fluctuations particularly occurred for householders age 25 to 44 years and 45 to 64 years. Householders under age 25 represented an increasing proportion of all households from 1950 to 1980, then declined in the 1980s and 1990s. Householders age 65 and over increased as a proportion of all householders from 1950 to 1990, then declined in the 1990s.

Householders age 45 and over represented the majority of all householders during the period 1950 to 2000. This group's share increased from 1950 to 1970, declined from 1970 to 1990, then increased again from 1990 to 2000. The share of all householders age 45 and over ranged from a low of 51 percent in 1990 to a high of 56 percent in 1970.

# Married-couple households declined from more than 3 out of every 4 households ( 78 percent) in 1950 to just over one-half ( 52 percent) in 2000. 

Households may be classified as either family households or nonfamily households. Within family households, married-couple households represent the most common type. Within nonfamily households, oneperson households (people living alone) represent the most common type. ${ }^{56}$

All types of households increased numerically between each census 1950 to 2000 (see Figure 5-8). The largest decadal increase in the number of households for 3 of the 4 major household types (all except married-couple households) occurred in the 1970s. The largest numerical increase of married-couple households occurred in the 1950s.

Although married-couple households remain the most common type of household, one-person households increased more than any other type during the 50-year period. Of the total increase of 63 million households, one-person households accounted for 23 million, married couples for 21 million, other family households for 13 million, and other nonfamily households for 6 million.

During each decade from 1950 to 2000, one of the nonfamily household types grew fastest. Other nonfamily households had the highest percentage increase every decade except for the 1960s, when one-person households grew fastest. Conversely, one of the family household types grew the slowest each decade. Married-couple households increased by the
${ }^{56}$ For definitions of households, householders, and various household types, see the Glossary.
lowest percentage each decade except for the 1950s, when other family households grew the slowest.

While all household types increased numerically from decade to decade, the slower increase of married-couple households resulted in a continual shrinking of the proportion of all U.S. households represented by mar-ried-couple households (see Figure 5-9). Between 1950 and 2000, married-couple households declined from more than 3 out of every 4 households ( 78 percent) to just over one half ( 52 percent) of all households.

Other family households declined as a proportion of all households in the 1950s, but increased every decade thereafter. By 2000, other family households represented about 1 of every 6 U.S. households (16 percent).

The shares of all U.S. households represented by both types of nonfamily households increased every decade during the period 1950 to 2000. The proportional share of one-person households increased more than any other type. In 1950, one-person households represented about 1 of every 10 households ( 9.5 percent). By 2000, one-person households comprised 1 out of every 4 households (26 percent). The proportional share of other nonfamily households also increased every decade. In 1950, other nonfamily households represented only 1.1 percent of households in the United States. By 2000, this category still represented the smallest share of the major household types, but it had increased to 6.1 percent of all U.S. households.

## All regions had increasing proportions of one-person households, reaching around one-fourth of all households in 2000.

As noted previously, the proportional share of all U.S. households represented by one-person households increased more than any other major household type, comprising one-fourth of all U.S. households (26 percent) by 2000. Similar regional trends occurred over the decades, with one-person households also representing about one-fourth of the households in each region by the end of the century (see Figure 5-10 and Appendix Table 14).

During the century, the Northeast, the Midwest, and the South all had similar proportions and patterns of growth of one-person households. The West also had an increasing proportion of one-person households 1900 to 2000, but its levels and pattern of change followed the most distinct trend of the regions.

In 1900, the West's proportion of one-person households ( 13 percent) far exceeded the proportions of the other regions, and it maintained the highest proportion of one-person households for each census, 1940
to 1970. Since 1980, the Northeast ranked 1 st among the regions in the proportion of one-person households.

The gap between the regions with the highest and the lowest proportion of one-person households narrowed with each census from 1900 to 1990, then became slightly wider in the 1990s. Differences between the Northeast's, the Midwest's, and the South's proportions of one-person households remained within a narrow range throughout the century, from 0.9 percentage points in 1900 to a maximum of 2.4 percentage points in 1970.

Although the West held the highest regional proportion of one-person households through 1970, the gap narrowed as every other region's increase in their proportion of one-person households exceeded the West's increase. By 1990 and again in 2000, the West had the smallest proportion of one-person households among the regions.

Figure 5-10.

## Percent One-Person Households by Region:

1900 and 1940 to 2000

Source: U.S. Census Bureau, decennial census of population, 1900, and decennial census of housing, 1940 to 2000.

# No state had at least 20 percent one-person households in 1940, but all states except Utah exceeded this level in 2000. 

The major growth in the proportion of one-person households occurred in the second half of the century. Data available from the population census of 1900 show that one-person households constituted at least 10 percent of all households in only 11 states, 10 western states, plus North Dakota (see Appendix Table 14). Although data are not available from the 1910 through 1930 censuses, data from the first census of housing in 1940 show the number of states with at least 10 percent one-person households remained essentially unchanged: Nevada, Montana, Washington, California, Oregon, Wyoming, Arizona, Colorado, and Idaho (just nine states). All of them had been among the 11 with at least 10 percent one-person households in 1900, and all were in the West. Of the 11 states with at least 10 percent one-person households in 1900, New Mexico's and North Dakota's proportions declined below 10 percent by 1940 (to 8.4 percent and 7.9 percent, respectively). The proportion of oneperson households increased in 34 states and the District of Columbia between 1900 and 1940 and declined in 14 states.

No state had at least 20 percent one-person households in 1940. The only states with at least 15 percent oneperson households in 1940 were Nevada (18 percent) and Montana ( 15 percent, see Figure 5-11).

While little growth occurred in the proportions of oneperson households in the first 40 years of the century, 30 years later, one-person households comprised at least 10 percent of the total number of households in all 50 states and the District of Columbia. Most states in 1970 had proportions of one-person households ranging between 15 percent and 20 percent of all households. Only California, the District of Columbia, and New York had at least 20 percent one-person households. All 11 states with less than 15 percent oneperson households were either in the South or the West.

The proportion of one-person households was higher in every state in 1970 than in 1940. Of the 48 states in 1940, the proportions of one-person households in the states with the 10 highest proportions increased but did not double. However, in 35 of the remaining 38 states (all except New Hampshire, New Mexico, and Utah), the proportion of one-person households more than doubled from 1940 to 1970.

Between 1970 and 2000, the proportions of one-person households again increased in every state and the District of Columbia. While no state's proportion of one-person households doubled from 1970 to 2000, one-person households represented at least 20 percent of all households in 49 of the 50 states by the end of the century, when only Utah (18 percent) had less than 20 percent one-person households.

In 2000, one-person households represented at least 25 percent of all households in 36 of the 50 states, where the proportion ranged narrowly from 25.0 percent to 29.3 percent, led by North Dakota. The next highest-ranking states in percentage one-person households were all in the Northeast-Rhode Island, New York, Massachusetts, and Pennsylvania. ${ }^{57}$

Among the 14 states with the lowest percentage (less than 25 percent) one-person households in 2000, four of these states-Nevada, California, Arizona, and Idaho-had ranked among the 10 states with the highest percentage one-person households in 1900 and 1940. Nevada and California also had ranked among the states with the 10 highest percentage one-person households as recently as 1980.

[^54]

Percent one-person households

Source: U.S. Census Bureau, decennial census of housing, 1940, 1970, and 2000.

## The number of one-person households increased every census, 1960 to 2000, for men, women, younger householders, and older householders.

From 1960 to 2000, the number of one-person households increased for both male and female householders and for householders both under age 65 and age 65 and over. Between 1960 and 2000, the number of men under age 65 living alone increased by 7.6 million, women under age 65 living alone by 5.7 million, men age 65 and over living alone by 1.5 million, and women age 65 and over living alone by 5.3 million (see Figure 5-12).

Of the four age-sex groups shown in Figure 5-12, the number of women age 65 and over living alone increased more than any other group in the 1960s, but the number of men under age 65 living alone increased the most for each decade thereafter.

The largest decadal increase in the number of one-person households for each group occurred in the 1970s, with the exception of men age 65 and over, who increased the most in the 1990s. The number of men under age 65 living alone more than doubled in the 1970s, the highest proportional increase in any decade during the period among the four groups considered. In part, the increases in one-person households in the 1970s coincide with the influx of the baby-boom generation into new households and increasing levels of divorce. Increases for women age 65 and over living alone throughout the period 1960 to 2000 suggest that growing numbers of women in this age group are living alone as a result of widowhood.

In 1960, more women under age 65 lived alone than did any of the other groups. In 1970, women age 65 and over living alone outnumbered people living alone in the other groups. In each census, 1980 to 2000, men under age 65 represented the age and sex group with the most one-person households. Men age 65 and over had both the fewest one-person households
and the least increase in one-person households each census, 1960 to 2000.

From 1970 to 2000, men under age 65 living alone increased their share of the total number of one-person households (see Figure 5-13). From 1960 to 1990, the proportion of one-person households composed of women under age 65 decreased.

Over the period 1960 to 2000, women under age 65 and men age 65 and over had their largest proportional shares of one-person households in 1960; women 65 and over in 1970, and men under age 65 in 2000.

Although both men and women householders under age 65 represented sizable proportions of all one-person households, these proportions were much less than these age groups' share of the total population. For example, while men under age 65 represented a range of 25 percent to 34 percent of all one-person households over the years 1960 to 2000, this age group represented 44 percent to 45 percent of the population during this same period. Similarly, women under age 65 represented from 29 percent to 34 percent of one-person households, but 44 percent to 46 percent of the population.

In contrast, men, and especially women, age 65 and over represented proportionally larger shares of oneperson households than they did of the total population. From 1960 to 2000, men age 65 and over represented just 4 percent to 5 percent of the total population, but a range of 8 percent to 12 percent of all one-person households. Women age 65 and over represented just 5 percent to 8 percent of the total population during this period, but a disproportionately higher range (27 percent to 33 percent) of the total number of one-person households.

Figure 5-13.
Distribution of One-Person Households by Age and Sex of Householder: 1960 to 2000

Source: U.S. Census Bureau, decennial census of population, 1960 to 2000.

# Older female householders were far more likely to live alone than younger female householders and than younger and older male householders. 

Older female householders had a much greater likelihood of living alone than did younger female householders or male householders, regardless of age (see Figure 5-14). In every census from 1970 to 2000, between 73 to 77 percent of all female householders age 65 and over lived alone.

Younger female householders were also more likely to live alone than both younger male householders and older male householders. In 1960 and 1970, 40 percent and 41 percent, respectively, of all female householders under age 65 lived alone, however, this proportion declined each census after 1970 to 29 percent in 2000.

From 1960 to 2000, the proportion of all male householders under age 65 living alone increased each census, from 4.7 percent to 16.9 percent, but this group was the least likely to be living alone. This fact derives from the very high proportion of men who are identified as the householder among married-couple households. ${ }^{58}$

[^55]The proportion of all male householders age 65 and over living alone also generally increased during the period 1960 to 2000, with a slight decline occurring in the 1970s. A higher proportion of male householders age 65 and over lived alone than male householders under age 65 at each census during the period, although the gap between these two groups reached its narrowest point at the end of the century. By 2000, 1 out of every 5 male householders age 65 and over lived alone.

The generally declining proportions of female householders under age 65 who lived alone, combined with increasing proportions of both under-65 and 65-andover male householders who lived alone, reduced the gap between these three groups to its narrowest point by 2000. However, the gap between the proportion of women householders under age 65 and those age 65 and over who lived alone widened, except in the 1990s.

Figure 5-14.
Percent One-Person Households Within Specific Age-Sex Groups: 1960 to 2000

Source: U.S. Census Bureau, decennial census of population, 1960 to 2000.

## Female householders increased as a proportion of total householders.

Female-maintained households represented an increasing proportion of all U.S. households from 1970 to 2000 (see Figure 5-15). In 1970, women represented about 1 of every 5 ( 21 percent) householders in the United States; by 2000, the proportion was more than 1 of every 3 (36 percent). However, different trends occurred among the major household types during the last 30 years of the century.

As noted earlier, all households may be broadly classified as either family households or nonfamily households. Family households may be further broken down into married-couple households and other family households. Similarly, nonfamily households may be separated into one-person households and other nonfamily households.

Prior to 1980, every U.S. population census automatically designated the husband as the householder of all married-couple families. Since then, either the husband or the wife may be the householder, depending on which one lists himself or herself as the first person on the questionnaire. From 1980 to 2000, the proportion of female householders in married-couple households increased, from 3.7 percent in 1980 to 12.9 percent in 2000 . In contrast, the proportion of female householders in each of the other major household types was lower in 2000 than in 1970.

Among the major household types, women represented the largest proportion of other family householders each census, 1970 to 2000. Female-maintained other family households declined as a proportion of all other family households, but still represented 75 percent of all such households in 2000. (This decline implies that male-maintained other family households increased as a percentage of all other family households.)

The proportion of one-person households maintained by women declined each census, 1970 to 2000, but remained the majority ( 57 percent) of all one-person households in 2000. Among other nonfamily households, women represented the majority of householders in 1970. However, this proportion fell substantially by 1980, then increased to the point that females maintained 42 percent of other nonfamily households in 2000.

The proportion of all family households with a female householder increased each census, from 11 percent in 1970 to 28 percent in 2000. In contrast, the proportion of female householders among all nonfamily households decreased each census, from 63 percent in 1970 to 54 percent in 2000. Furthermore, although the share of female householders among married-couple households increased, the share of female householders of all households other than married couples declined, from 69 percent in 1970 to 61 percent in 2000.

Figure 5-15.
Percent of Households With a Female Householder by Type of Household: 1970 to 2000

(x) Not applicable.

Source: U.S. Census Bureau, decennial census of population, 1970 to 2000.

# For total, married-couple, and other family households, the proportion of female householders among Black householders exceeded the proportion of female householders among householders of any other race or of Hispanic householders. 

Between 1980 and 2000, an increasing trend occurred in the proportion of householders who were women for every race and Hispanic-origin group (see Figure 5-16). However, while strong similarities occurred in the patterns of change from census to census, important differences among the groups in 1980 remained in 2000.

The proportion of all householders who were female increased for each race and Hispanic group from 1980 to 2000. Women consistently represented the highest proportion of householders among Blacks, followed by American Indians and Alaska Natives. Among all Black householders, women have been more likely than men to be identified as the householder since 1990. Throughout the 20-year period, the lowest proportion of female householders was found among Asian and Pacific Islander households.

Women also represented an increasing proportion of all married-couple householders for every race and Hispanic-origin group since 1980, when women first became eligible to be identified as the householder of a married-couple household. Black women householders accounted for a higher proportion of marriedcouple households than women of any other race or Hispanic origin for each census, 1980 to 2000. White (and White non-Hispanic) women and Asian and Pacific Islander women were least likely to be identified as the householder within married-couple households.

Women were listed as the householder in the vast majority of other-family households for every race and Hispanic-origin group between 1980 and 2000. In 1980, females represented at least three-fourths of all
other-family householders for every race and Hispanicorigin group, except for Asians and Pacific Islanders. Although Asian and Pacific Islander other-family households had the lowest proportion of female householders throughout the period, they still represented around two-thirds of these households. Blacks had the highest proportion of female-maintained other-family households, with women maintaining 84 percent to 86 percent of Black other-family households throughout the period.

Among nonfamily households, the direction of change between 1980 and 2000 in the proportion of female householders varied by group. Female householders represented a slightly declining proportion of nonfamily householders between 1980 and 2000 among White, American Indian and Alaska Native, and Hispanic householders, and a slightly increasing proportion among Black and Asian and Pacific Islander householders.

In 1980 and 2000, White female householders and Black female householders (and in 2000, White nonHispanic female householders) represented slightly over one-half of all nonfamily householders. In contrast, male householders represented the majority of nonfamily householders for every other group. Among the groups, Black female householders represented the highest proportion of married-couple householders and other-family householders, while White (and White non-Hispanic) female householders represented the highest proportion of nonfamily householders.

Figure 5-16.
Percent Female Householders of Total Householders by Type of Household and Race and Hispanic Origin of the Householder: 1980 and 2000
(Percent)

Total households

Married-couple households

Other family households

Nonfamily households

[^56]
# Each decade from 1960 to 2000, married-couple households were less likely to include children under age 18, while male family households with no wife present were more likely to include children under age 18. 

Family households consist of married-couple households and other family households. Other family households include those maintained by a man with no wife present or by a woman with no husband present. Family households also may be characterized by the presence or absence of one or more of the householders' own children. ${ }^{59}$ The trend in the proportion of family households with their own children under age 18 varied considerably by family type during the period 1950 to 2000 (see Figure 5-17 and Appendix Table 15).

Among married-couple households, the proportion with their own children under age 18 has declined since 1960. In 1960, 3 out of every 5 married-couple households ( 59 percent) had at least one own child under age 18. By 1990 (and in 2000), less than half (46 percent) of married-couple households had any own children under age 18.

Among female family households with no husband present, the proportion with their own children under age 18 increased from 1 out of every 3 (34 percent) households in 1950 to 3 out of every 5 households (60 percent) by 1980. This proportion declined slightly in the 1980s, then increased slightly in the 1990s, while remaining fairly stable.

Among male family households with no wife present, the proportion with their own children under age 18 increased in every decade from 1950 to 2000. In 1950, only 1 out of every 5 (19 percent) male family households with no wife present had own children under age 18. By 2000, half ( 50 percent) of these households had own children under age 18.

In addition to the overall differences among family types, the trends in the age composition of the children within each type also display some important differences. For example, among male family households with no wife present, the proportions of these house-

[^57]holds including their own children under age 6 (and no other own children) increased in every census from 1960 to 2000. In fact, by the end of the century, male family households with no wife present were more likely to have children under age 6 only than either mar-ried-couple households or female family households with no husband present. In contrast, the trend in the proportion of married-couple households with children under age 6 only went in the opposite direction, declining from 15 percent in 1960 to 11 percent in 2000.

The trends in the proportions of households with their own children only within the ages 6 to 17 years fluctuated for each family type. Among married-couple households, the proportion remained within a narrow range during the period 1960 to 2000, from 24 percent to 28 percent. For female family households with no husband present, the proportion with children only within the ages 6 to 17 increased to a peak of 39 percent in 1980, declined during the 1980s to 34 percent in 1990, then increased in the 1990s to 37 percent in 2000. Among the family types, female family households with no husband present were the most likely to have children ages 6 to 17 years only in the household. For male family households with no wife present, the proportion generally increased from 1960 to 2000, with one slight decline in the 1980s.

The proportion of married-couple households with children under age 6 and children age 6 to 17 generally declined, from about one-fifth ( 18 percent) of marriedcouple households in 1960 to just one-tenth (10 percent) in 2000. In comparison, the proportion of female family households with no husband present and with their own children under age 6 and age 6 to 17 remained steady at around one-tenth during the 40-year period. The percentage of male family households with no wife present and with children under age 6 and age 6 to 17 generally increased during the period, although they remained the family type least likely to have children of both age groups in the household.

${ }^{1}$ Density levels for the United States and the West region exclude Alaska and Hawaii for 1900 through 1950. Data for Alaska and Hawaii prior to 1960 were collected for these territories in each decennial census of population.

Note: Density levels are based on Census 2000 land area measurements.
Source: U.S. Census Bureau, Geography Division; decennial census of population, 1900 to 2000.

Table 3. Population by Metropolitan Status for the United States, Regions, and States: 1900 to 2000
Part A. Metropolitan

${ }^{1}$ Data for 1930 refer to age group 35 to 44 years.
${ }^{2}$ Data for 1930 refer to age group 45 to 54 years.
${ }^{3}$ Data for 1930 refer to age group 55 to 64 years.
${ }^{4}$ Data for 1930 and 1940 refer to age group 65 to 74 years.
Note: Data based on sample for 1950 and 1960 for Black population, and for 1950, 1960, and 1970 for American Indian and Alaska Native and Asian and Pacific Islander populations. See Appendix C, Sources and Quality of Data, for discussion of race concepts and changes in classification from 1900 to 2000.

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

Table 12. Housing Units by Occupancy Status and Tenure for the United States, Regions, and States: 1900 to 2000

NA Not available.
${ }^{1}$ Data for 1910 and 1920 include a small number of quasi-households and are not strictly comparable with data for other years.
${ }^{2}$ Data for 1900 derived by assuming all group quarters $(223,750)$ had 7 or more people.
Note: Numbers in italics are based on sample data. In 1960, two numbers for both the number of households and the total household population are shown, since one total is based on 100-percent data and the other is based on sample data. In 1950, two total household numbers are shown. The separate computer processing of the population data and the housing data from the 1950 census produced two different totals from the 100-percent data: $42,857,335$ from the census of population and $42,826,281$ from the census of housing.

Source: U.S. Census Bureau, decennial census of population, 1900 to 2000; decennial census of housing, 1940 to 2000.

Table 14. Households by Size for the United States, Regions, and States: 1900 to 2000 Part A. Total Households

## NA Not available.

${ }^{1}$ Data for 1970 represent householders age 45 to 64 years.
${ }^{2}$ Data for 1980 represent householders age 75 years and over.
Note: Numbers in italics are based on sample data. In 1960, 1970, and 1980, two numbers for one-person households are shown. In 1960, this results from data tabulations based on two different samples (7,074,971 from a 25 -percent sample of the housing census and 7,063,326 from a 5 -percent sample of the population census). In 1970 and 1980, one total is based on 100-percent data and the other is based on sample data. In 1950 and 1960, family households could include more than one family. For 1950, the data in the table represent primary families and reflect the exclusion of secondary families from the published distributions of total family households and families to increase comparability. In 1960, available data only permitted this adjustment to the number of family households based on a 25 -percent sample. The distribution of the number of families by type and presence of own children under 18 shown in 1960 includes both primary and secondary families and is based on a 5-percent sample.

## Appendix B.

## GLOSSARY

Age - The number of complete years an individual has lived. The age classification is based on the age of the person at his or her last birthday.

Age Structure - The distribution of a population by age, usually in 5-year age groups.

Aging - In this report, used to indicate an increase in the proportion of the population in the older ages. May also be an increase in the median age of the population.

American Indian and Alaska Native - Term used in Census 2000 for a person having origins in any of the original peoples of North and South America (including Central America), who maintains tribal affiliation or community attachment. Over time, the terminology used for this race category changed to reflect the data collected during each decennial census. The terms used included Indian; American Indian; American Indian, Eskimo, and Aleut; and American Indian and Alaska Native. For Census 2000, American Indian and Alaska Native includes people who classify themselves as described below.

American Indian - Includes people who indicated their race as American Indian, entered the name of an Indian tribe, or reported such entries as Canadian Indian, French-American Indian, or Spanish-American Indian.

Alaska Native - Includes written responses of Eskimos, Aleuts, and Alaska Indians as well as entries such as Arctic Slope, Inupiat, Yupik, Alutiiq, Egegik, and Pribilovian. The Alaska tribes are the Alaskan Athabaskan, Tlingit, and Haida. The terminology included in Census 2000 is derived from the American Indian Detailed Tribal Classification List for the 1990 census, expanded to include the individual Alaska Native Villages.

For the purpose of this report, people who were classified or classified themselves as Indian or American Indian, Eskimo, and Aleut prior to Census 2000 were classified as American Indian and Alaska Native in order to maintain consistency in terminology.

Asian - Term used in Census 2000 for a person having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent (for example, Cambodia, China, India, Japan, Korea, Malaysia, Pakistan, the Philippine Islands, Thailand, and Vietnam). See Asian and Pacific Islander.

Asian and Pacific Islander - For the purpose of this report, the 1990 designated term Asian and Pacific Islander was used for the entire century to identify respondents who were enumerated as or identified themselves as any of the Asian, Native Hawaiian, or Pacific Islander races. The term Asian and Pacific Islander was used in order to maximize data comparability over the century despite changes that took place in the terms used to describe each race, the race categories collected on the questionnaire, and the manner in which the data was tabulated.

In 1900, the only individual Asian and Pacific Islander categories available were Chinese and Japanese. From 1910 to 1940, the racial classification included an Other race category with write-in responses to obtain separate figures on other groups such as Filipinos and Koreans. In this report, each detailed Asian and Pacific Islander group tabulated separately in censuses prior to 1950 was classified into the total Asian and Pacific Islander group. However, in the 1950 census, the only Asian and Pacific Islander categories published separately for every state were Chinese and Japanese. Other people who were Asians and Pacific Islanders who did not fit into one of these two categories were classified under the Other race category. In 1960 and 1970, the category Asian and Pacific Islander in this report includes Chinese, Japanese, and Filipino. (Separate categories for Hawaiians and Part-Hawaiians were included on the 1960 census questionnaire in Hawaii only and, in the 1970 census, a separate classification for Koreans and Hawaiians was included in tabulations for the conterminous United States and Hawaii.) In 1980, Asian and Pacific Islanders included Chinese, Japanese, Filipino, Korean, Asian Indian, Vietnamese, Hawaiian, Guamanian, and Samoan. In 1990, Asian and Pacific Islanders included more detailed categories, plus all other Asian and all other Pacific Islander classifications.

The 1990 Asian and Pacific Islander category was divided in Census 2000 into two groups: Asian and Native Hawaiian and Other Pacific Islander. In order to maintain data comparability, these two groups (race alone) were added together under the category Asian and Pacific Islander. See Asian and Native Hawaiian and Other Pacific Islander.
Average Household Size - A measure obtained by dividing the number of people in households by the total number of households (or householders).
Baby Boom - A term used to refer to the period of relatively high fertility after World War II, commonly considered as the period from 1946 to 1964. People born during this period are often referred to as "baby boomers," the baby-boom generation, or the babyboom cohort.
Baby Bust - A term used to refer to the period of declining fertility following the baby boom from 1965 to 1976.

Birth Cohort - A group of individuals born in the same calendar year or group of years.
Birth Rate - The average annual number of births during a year per 1,000 population at midyear. Also known as the crude birth rate.

Black (or African American) - A person having origins in any of the Black racial groups of Africa. Over time, the terminology used for this race category has included Black, Negro, and African American. It includes written entries such as African American, Afro American, Kenyan, Nigerian, or Haitian.

Census Coverage - The difference between the true population and the number of population members included in the census, regardless of whether they were properly classified. A smaller census count than the true population implies net undercoverage and a larger census count than the true population implies net overcoverage of the population.

Central City - The largest city in a metropolitan area. Additional cities qualify if specified requirements are met concerning both population size and levels of employment. See Metropolitan Area (MA) and Suburb.

Components of Population Change - The components are: fertility, mortality, and migration.
Consolidated Metropolitan Statistical Area (CMSA) - A geographic entity defined by the Federal Office of Management and Budget (OMB) for use by federal statistical agencies. An area becomes a CMSA if: it meets the requirements to qualify as a metropolitan
statistical area (MSA); it has a population of $1,000,000$ or more; its component parts are recognized as primary metropolitan statistical areas (PMSAs); and local opinion favors the designation. The term CMSA was introduced in 1983 and replaced what were formerly known as Standard Consolidated Areas and Standard Consolidated Statistical Areas in previous censuses. See Standard Consolidated Area (SCA) and Standard Consolidated Statistical Area (SCSA).
Conterminous States - The coterminous 48 states and the District of Columbia; that is, the United States excluding Alaska and Hawaii.
Crude Birth Rate - See Birth Rate.

## Crude Death Rate - See Death Rate.

Death Rate - The average annual number of deaths during a year per 1,000 population at midyear. Also known as the crude death rate.

Decennial Census - The census of population and housing, taken by the Census Bureau in years ending in 0 (zero). Article I of the U.S. Constitution requires that a census be taken every 10 years for the purpose of reapportioning the U.S. House of Representatives. The first census of population occurred in 1790; the census of housing has been conducted since 1940.

Depression Era - For the purpose of this report, the period of time from the 1930 to the 1940 census, or the decade of the 1930s.
Elderly - For the purpose of this report, elderly refers to people age 65 years and over. This term is used for the chronological demarcation of age categories and is not meant to obscure the diversity of this broad age group, spanning more than 40 years of life.
Emigration - The movement of population out of its original country of residence. For example, a person who emigrates from the United States leaves the United States to live in another country.
Family Household (Family) - A family household consists of a householder and one or more people living together in the same household who are related to the householder by birth, marriage, or adoption. All people in a household who are related to the householder are regarded as members of his or her family. A family household may contain people not related to the householder, but those people are not included as part of the householder's family in census tabulations. In 1950 and 1960, a household enumerated in the census could contain more than one family. Thus, there were more families than family households. From 1970 to 2000, each family household in the
census could contain only one family, resulting in an equal number of families and family households. Not all households contain families since a household may be comprised of a group of unrelated people or one person living alone. See Nonfamily Household.

Female Householder, No Husband Present - A woman maintaining a family household with no husband of the householder present.

Group Quarters - Dwelling places that are not housing units. These include both institutions (such as prisons) and other group quarters (such as college dormitories). Compare Housing Unit.

Group Quarters Population - All people who are not living in households. There are two types of group quarters populations: institutionalized and noninstitutionalized. Examples of institutionalized populations are people living in correctional institutions, nursing homes, (psychiatric) hospitals or wards, and juvenile institutions. Examples of noninstitutionalized group quarters populations are people living in college dormitories and military quarters. Compare Household Population.

Growth Rate - The average annual percent change in the population, resulting from a surplus (or deficit) of births over deaths and the balance of migrants entering and leaving an area. The rate may be positive or negative. Also known as population growth rate or average annual rate of growth.

## Head of Household - See Householder.

Hispanic or Latino Origin - People who identify with the terms Hispanic or Latino are those who classify themselves in one of the specific Hispanic or Latino categories listed on the decennial census ques-tionnaire-"Mexican, Mexican-Am., Chicano," "Puerto Rican," or "Cuban"-as well as those who indicate that they are "other Spanish, Hispanic, or Latino." Origin can be viewed as the heritage, nationality group, lineage, or country of birth of the person or the person's parents or ancestors before their arrival in the United States. People who identify their origin as Spanish, Hispanic, or Latino may be of any race.

Homeownership Rate - The proportion of households that are owner occupied. It is computed by dividing the number of owner-occupied housing units by the total number of occupied housing units, times 100.

Household - One person or a group of people living in a housing unit. Compare Group Quarters.

Household Population - The total number of people living in households. The household population added to the group quarters population equals the total population. Compare Group Quarters Population.

Householder - The householder refers to the person (or one of the people) in whose name the housing unit is owned or rented (maintained) or, if there is no such person, any adult member, excluding roomers, boarders, or paid employees. Since 1980, if the house was owned or rented jointly by a married couple, the householder could be either the husband or the wife. Prior to 1980, the term head of household was used and the husband was always classified as the head of a married-couple household if the husband was living with his wife at the time of the census. The person who designates himself or herself as the householder (or head of household) is the "reference person" to whom the relationship of all other household members, if any, is recorded.

Housing Unit - A housing unit is a house, an apartment, a mobile home, a group of rooms, or a single room that is occupied, or intended for occupancy, as separate living quarters. Separate living quarters are those in which the occupant(s) live separately from any other people in the building and which have direct access from outside the building or through a common hall. Compare Group Quarters.

Immigration - The movement of population into a new country of residence. For example, a person who immigrates to the United States enters from another country to live in the United States.

Infant Mortality Rate - The number of deaths to infants less than 1 year of age during a year (or period) per 1,000 births.

Intercensal - Refers to the period between two consecutive decennial censuses.

Internal Migration - A relatively permanent change in residence between specifically designated political or statistical areas within the boundaries of a given country. For the purpose of this report, internal migration refers to migration within the United States.

International Migration - A relatively permanent change in residence across national boundaries.

Less Developed Countries (LDCs) - The "less developed" countries include all of Africa, all of Asia except Japan, the Transcaucasian and Central Asian republics of the New Independent States (NIS), all of Latin America and the Caribbean, and all of Oceania, except Australia and New Zealand.

Life Expectancy at Birth - The average number of years a hypothetical group of people born in a specified year would live if they experienced over their lifetime the mortality rates at each year of age that occurred in the specified year (e.g., 1900 or 2000).

Male Householder, No Wife Present - A man maintaining a family household with no wife of the householder present.

Married-Couple Household - A family household maintained by a householder and his/her spouse in which the spouse lives in the same household with the householder. See Family Household.

Mean Center of Population - The point at which an imaginary, flat, weightless, and rigid map of the United States would balance perfectly if weights of identical value were placed on it so that each weight represented the location of one person on the date of the census.

Median Age - The median divides the age distribution into two equal parts, one-half of the population falling below the median age and one-half above the median.

Median Center of Population - The median center is located at the intersection of two median lines, a north-south line constructed so that half of the country's population lives east and half lives west of it, and an east-west line selected so that half of the country's population lives north and half lives south of it.

Metropolitan Area (MA) - The general concept of a metropolitan area is that of a large population nucleus, together with adjacent communities having a high degree of social and economic integration with that nucleus. The terminology used to describe this concept changed from census to census over the course of the century. The terms used included: metropolitan district, standard metropolitan area (SMA), standard metropolitan statistical area (SMSA), and metropolitan area (MA). The term metropolitan area was formally used for the first time in the 1990 census. However, for the purpose of this report, the term metropolitan area is used for every decade from 1910 to 2000 in order to maintain consistency in terminology. See also Metropolitan District, Standard Consolidated Area (SCA), Standard Consolidated Statistical Area (SCSA), Consolidated Metropolitan Statistical Area (CMSA), Standard Metropolitan Area (SMA), and Standard Metropolitan Statistical Area (SMSA).

Metropolitan District - A statistical area comprising a central city and adjacent incorporated places, densely settled Minor Civil Divisions (MCDs) and, in
some cases, enumeration districts (EDs). It was used in the 1910, 1920, 1930, and 1940 decennial censuses (with changes in the underlying criteria) and was a forerunner of the Metropolitan Area and Urbanized Area concepts.

Midwest - One of the four regions in the United States. Twelve states compose the Midwest: Illinois, Indiana, lowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin.

Migration - A relatively permanent change in residence between specifically designated political or statistical areas or between type-of-residence areas.

Minority Population - For the purpose of this report, the Minority population is defined as all people who are races other than White (White alone in Census 2000) or are Hispanic. In this report, Minority population trends cover the period 1980 to 2000, which coincides with the censuses when data on Hispanic or Latino origin are available on a 100-percent basis.

More Developed Countries (MDCs) - The "more developed" countries and areas include all of North America and Europe (including the Baltics and the four European republics of the New Independent States: Russia, Ukraine, Belarus, and Moldova), plus Japan, Australia, and New Zealand. This category matches the "more developed" classification employed by the United Nations.

Native Hawaiian and Other Pacific Islander - Term used in Census 2000 for a person having origins in any of the original peoples of Hawaii, Guam, Samoa, or other Pacific Islands. Data on Native Hawaiians and Other Pacific Islanders were collected in different forms prior to Census 2000, but the category Native Hawaiian and Other Pacific Islander was not used. In 1980 and 1990, most census tabulations presented data on Native Hawaiians and Other Pacific Islanders under the term Pacific Islander, and they were included in the broader race category Asian and Pacific Islander. In Census 2000, the 1990 category Asian and Pacific Islander was broken into two categories, Asian and Native Hawaiian and Other Pacific Islander. For the purpose of this report, the Native Hawaiian and Other Pacific Islander population was added to the Asian population to create the category Asian and Pacific Islander in order to maintain data comparability with data from previous censuses. See Asian and Pacific Islander.

Natural Increase - The number of births minus the number of deaths.

Nonfamily Household - A household composed of a person living alone or a household of two or more people where all are unrelated to the householder. Compare Family Household.

Nonmetropolitan Area - All areas not located in a metropolitan area (or metropolitan district prior to 1950).

Northeast - One of the four regions in the United States. Nine states compose the Northeast: Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont.

Occupancy Rate - The proportion of total housing units that are occupied. Compare Vacancy Rate.

Occupied Housing Unit - A housing unit is classified as occupied if it is the usual place of residence of the person or group living in it at the time of enumeration, or if the occupants are only temporarily absent, that is, away on vacation or business.

One-Person Household - A household composed of one person living alone.

Other Family Household - Other family households consist of households maintained by a woman (no husband present) living with at least one other relative, or maintained by a man (no wife present) living with at least one other relative. Other family households comprise all family households excluding mar-ried-couple households. In order to qualify as a family household, the household must contain a householder and one or more people who are related to the householder by birth, marriage, or adoption. See also Family Household.

Other Nonfamily Household - Other nonfamily households consist of households of two or more members, none of whom is related to the householder. Other nonfamily households include all nonfamily households excluding one-person households. See also Nonfamily Household.

Own Children - Children under 18 years of age who are sons or daughters of the householder by birth, marriage (a stepchild), or adoption. Prior to 2000, 100-percent data on own children included only children who were never married. In the 100-percent data from Census 2000, own children included all children under 18 years of age, regardless of marital status.

Owner-Occupied Housing Unit - A housing unit is owner occupied if the owner or co-owner lives in the unit even if it is mortgaged or not fully paid for.

Population Density - A measurement calculated by dividing population by land area (people per square mile or square kilometer of land area). Population density is used as a measurement of the level of concentration of population in a particular geographic area.

Population Estimates - A calculation of population size derived for current or past dates using data from population censuses, administrative records, sample surveys, and/or other sources.

Population Projections - A calculation of population size derived for future dates using assumptions about future trends and data from population censuses, administrative records, sample surveys, and/or other sources.

Population Pyramid - A specialized type of graph designed to give a detailed picture of the age-sex structure of a population, indicating single ages, 5year age groups, or other age groups. Pyramids may be constructed on the basis of either numbers or percent distributions.

Race - Over the course of the century, the concept of race as used by the Census Bureau has reflected enumerator identification and/or self-identification of people. Prior to 1980, race was determined either solely by the observation of the enumerator or by a combination of enumerator observation and self-identification. These categories reflect social usage and should not be interpreted as being scientific or anthropological in nature. Furthermore, the race categories include both racial and national-origin groups.

Race Alone Population - The population comprised of people who responded to the race question on the Census 2000 questionnaire by indicating only one race. The race alone population was introduced in Census 2000 because respondents were given the option of selecting more than one race for the first time in census history. The six categories that make up this population are White alone, Black or African American alone, American Indian and Alaska Native alone, Asian alone, Native Hawaiian and Other Pacific Islander alone, and Some other race alone.

Race Alone or in Combination Population - In Census 2000, respondents who reported only one race together with those who reported that same race plus one or more other races are combined to create the race alone or in combination categories. The six categories that make up the race alone or in combination population are White alone or in combination, Black or African American alone or in combination, American Indian and

Alaska Native alone or in combination, Asian alone or in combination, Native Hawaiian and Other Pacific Islander alone or in combination, and Some other race alone or in combination. The alone or in combination categories are tallies of responses rather than respondents. That is, the alone or in combination categories are not mutually exclusive. Individuals who reported two races were counted in two separate and distinct alone or in combination race categories, while those who reported three races were counted in three categories and so on.

Race in Combination Population - The population of people for a specified race who responded to the Census 2000 question on race by choosing more than one race category. The race in combination population was introduced in Census 2000 because respondents were given the option of selecting more than one race for the first time in census history.

Rate of Natural Increase - The difference between the crude birth rate and the crude death rate.

Region - One of four geographically defined areas in the United States. The four regions in the United States are Northeast, Midwest, South, and West. For a listing of the states in each region, see the separate region names in the glossary.

Renter-Occupied Housing Unit - All occupied housing units which are not owner occupied, whether they are rented for cash or occupied without payment of cash rent.

Seasonal, Recreational, or Occasional Use Housing Units - Seasonal, recreational, or occasional use housing units include vacant units used or intended for use only in certain seasons, for weekends, or other occasional use throughout the year. Interval ownership units, sometimes called shared ownership or time-sharing condominiums, are included in this category.

Sex - Either male or female.
Sex Ratio - The sex ratio is an indication of the balance of males and females in a population. It is calculated by dividing the male population by the female population and multiplying by 100.

Some Other Race - Includes all other responses not included in the White, Black or African American, American Indian and Alaska Native, and Asian and Pacific Islander race categories described above (from 1950 to 1990) and, in Census 2000, includes all responses not included in any of the race alone or race in combination categories, which include any of the
following: White, Black or African American, American Indian and Alaska Native, Asian, and Native Hawaiian and Other Pacific Islander. Respondents providing write-in entries such as multiracial, mixed, interracial, or a Hispanic/Latino group (for example Mexican, Puerto Rican, or Cuban) in the Some other race category are included in this category.

South - One of the four regions in the United States. Sixteen states and the District of Columbia compose the South. The states are Alabama, Arkansas, Delaware, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia.

Standard Consolidated Area (SCA) - The SCA was a forerunner of the consolidated metropolitan statistical area (CMSA). Two SCAs (for the New York and Chicago areas) existed between 1959 and 1975. These SCAs were combinations of standard metropolitan statistical areas (SMSAs), although the New York SCA also included two counties in New Jersey that were not within any SMSA. The SCA was replaced by the standard consolidated statistical area (SCSA). See Consolidated Metropolitan Statistical Area (CMSA).

Standard Consolidated Statistical Area (SCSA) The SCSA was a forerunner of the consolidated metropolitan statistical area (CMSA). An SCSA was a combination of two or more standard metropolitan statistical areas (SMSAs) that had substantial commuting between them and where at least one of the SMSAs had a population of $1,000,000$ or greater. SCSAs were first defined in 1975 and used until June 1983. See Consolidated Metropolitan Statistical Area (CMSA).

Standard Metropolitan Area (SMA) - SMA was the first term used for official metropolitan areas as defined by the then Bureau of the Budget in 1949 for the 1950 decennial census. The term was used until 1959, when the term standard metropolitan statistical area (SMSA) was adopted. See Metropolitan Area (MA).

Standard Metropolitan Statistical Area (SMSA) In 1959, the term SMSA replaced standard metropolitan area (SMA) for the official metropolitan areas defined by the then Bureau of the Budget. The term SMSA was used until metropolitan definitions were redefined in 1983. See Metropolitan Area (MA).

Suburb - For the purpose of this report, the area inside a metropolitan area but outside the central city. See Metropolitan Area (MA) and Central City.

Tenure - Tenure refers to whether a housing unit is owner or renter occupied.

Two or More Races Population - People in Census 2000 who provided more than one race response either by checking two or more race response check boxes, by providing multiple write-in responses, or by some combination of check boxes and write-in responses. There are 57 possible combinations of two, three, four, five, or six races.

Vacancy Rate - The percentage of total housing units that are vacant.

Vacant Housing Unit - A housing unit is vacant if no one is living in it at the time of enumeration, unless its occupants are only temporarily absent. Units temporarily occupied at the time of enumeration entirely
by people who have a usual residence elsewhere are also classified as vacant.

West - One of the four regions in the United States. Thirteen states compose the West: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming

White - A person having origins in any of the original peoples of Europe, the Middle East, or North Africa. It includes people who indicate their race as White or report entries such as Irish, German, Italian, Lebanese, Near Easterner, Arab, or Polish.

## Appendix C. <br> SOURCES AND QUALITY OF DATA

## BACKGROUND AND GENERAL SCOPE

Every population census of the United States from 1790 to 1930 collected all information on a 100-percent basis. Beginning with the 1940 census of population and housing, the Census Bureau collected information on both a 100-percent and a sample basis.

The scope of information included in the population trends discussed in this report is limited to those items collected on a 100-percent basis in Census 2000. So, for example, although marital status information previously had been collected on a 100-percent basis, Census 2000 obtained marital status data on a sample basis only, and thus such information was not included here. On the other hand, some items, particularly related to housing and households, although collected on a 100-percent basis, were only available in publications of earlier censuses on a sample basis. In such cases, these items are included within the scope of this report, and sample data are indicated by the use of italics in the Appendix Tables.

In any large-scale statistical operation, such as the U.S. decennial census, human and machine-related errors occur. These errors are commonly referred to as nonsampling errors. Such errors include not enumerating every household or every person in the population, not obtaining all required information from the respondents, obtaining incorrect or inconsistent information, and recording information incorrectly. In addition, errors can occur during the manual and electronic processing of the data. Over the course of the 20th century, the U.S. Census Bureau continuously developed and improved techniques to reduce various types of nonsampling errors during all phases of data collection and processing. Implementation of such procedures improved census coverage and the quality of the final data.

In a few cases, sample tabulations of data were used from censuses before Census 2000, as noted above. Estimates derived from sample data are expected to be different from the 100-percent figures because they are subject to sampling and nonsampling errors. Sampling error in data arises from the selection of persons and housing units to be included in the sample.

The deviation of a sample estimate from the average of all possible samples is called the sampling error. For a detailed discussion of sampling and nonsampling error in Census 2000, see
www.census.gov/prod/cen2000/doc/sf3.pdf, and
www.census.gov/prod/cen2000/doc/sf1.pdf, respectively.

## POPULATION TOTALS

The total populations of the United States shown for each census, 1900 to 2000, represent the totals published at the time each census was conducted. That is, no totals have been modified or adjusted to incorporate any subsequent postcensal corrections.

Population totals shown for the countries and regions of the world were obtained from the U.S. Census Bureau's International Data Base. These estimates were based on the latest available population census, fertility, mortality, and international migration data for each country.

## GEOGRAPHIC DATA

## States and Regions

Data for states and regions represent the totals for each area as reported by the results of the census of population. Population totals for Alaska and Hawaii are shown as collected by each census throughout the century but are not included in the West region nor the United States totals for 1900 through 1950. Beginning with 1960, the first census year after Alaska and Hawaii gained statehood, population characteristics and all West region and U.S. totals include these states.

Population totals (and characteristics) are included for the conterminous 48 states and the District of Columbia for every census, 1900 to 2000. This includes the populations of the Arizona and New Mexico territories prior to their statehood in 1912, since these areas were included in the national population totals for these years in the original census volumes. In addition, the population of the Indian territory was included in the
state total for Oklahoma (statehood in 1907) for the census of 1900. Each of these totals also is included in the United States and regional populations for all census years.

## Metropolitan

Metropolitan area data in this report include the information tabulated for areas defined as metropolitan districts from 1910 to 1940 (plus cities and adjacent territory for cities of 100,000 to 200,000 population in 1910 and in 1920), as well as the areas defined as metropolitan after each census since 1950 using the formal criteria and standards established by the Office of Management and Budget (OMB).

The changing criteria and definitions of metropolitan districts and metropolitan areas (referred to under several name variations) make comparability over time problematic. However, the broad findings regarding the trends of the total metropolitan population generally hold, regardless of the data issues.

The 1910 to 1940 data represent metropolitan district information as published at the time of each census. These districts primarily were defined based on central cities and surrounding minor civil divisions meeting a population density threshold. For 1910 and 1920, the metropolitan populations shown also include cities of 100,000 to 200,000 population and their adjacent territory at the time of each census.

Since 1950, metropolitan areas have been defined using counties as the basic geographic unit (with the exception of New England states, where towns and cities have been used). In general, commuting patterns and a minimum population size of a central city have been part of the formal definition of metropolitan areas. Congressionally mandated exceptions and other modifications have occurred since the establishment of metropolitan areas, and a two-level hierarchy concept has been used since a New York standard consolidated area (SCA) and a Chicago SCA were identified in the 1960 census using criteria established in 1959.'

Metropolitan data are shown in this report by state and region. Thus, when a specific metropolitan area included population in multiple states, the portions of the population living in the individual states are included in the metropolitan population of the appropriate state. For 1930 to 2000, these data can be derived from published census volumes. Since infor-

[^73]mation needed to separate the portions of each area's population by state was not available for 1910 and 1920, unpublished data and research were used to classify metropolitan proportions in some areas. ${ }^{2}$

## Land Area

This report includes calculations of population density for the United States, regions, and states, derived as the average population per square mile of land area. The land area of each state as measured for Census 2000 was used as the denominator for all population density calculations, since only trivial changes have occurred in the land area of states over the century, and since a large portion of such changes reflects improvements in the measurement of land area, rather than actual changes. As a result, some calculated values of population density in this report pertaining to earlier census years may slightly differ from those originally calculated at the time of the census.

Since Alaska represents the largest state in terms of land area, its inclusion or exclusion has a large impact on the total density of the United States. For this reason, the report includes an illustration of population density levels from 1900 to 1950 both including and excluding Alaska (and Hawaii).

## Center of Population

This report includes trends of two concepts of the center of population, namely, the mean center of population and the median center of population. (For definitions of these terms, see the Glossary.) The Geography Division of the U.S. Census Bureau provided the results of the calculation of the location of the mean and median centers. Using formulas provided by the Geography Division, the authors calculated the total shift in the mean center of population to the South and West over the course of the century.

## AGE AND SEX DATA

A question on age and sex has been asked in every U.S. census since the first one in 1790. The census of 1850 was the first to collect information on the specific age of every individual in the United States.

Age data may suffer from numerous reporting problems, including coverage error, failure to report age, and misreporting of age. Coverage errors include people who are missed in the census and those who are

[^74]erroneously included (counted more than once). Levels of net coverage of the population typically show particular patterns by age. That is, some ages tend to have higher levels of underenumeration in censuses than other ages. For example, children under age 5 tend to have relatively higher levels of underenumeration. Misreporting of age may occur as a result of age heaping (the tendency to favor particular digits in the reporting of age, such as 0 or 5) or age exaggeration (the tendency to inflate one's age, particularly at very advanced ages).
The misreporting of data on sex generally is negligible. The quality of the reporting of this item ranks among the highest among all census items collected. Although misreporting is minimal, the quality of data on sex collected in censuses is affected by differential completeness of coverage of the two sexes. In general, the male population in the United States tended to have higher levels of underenumeration than the female population.
The age data used in this report are, with minor exceptions, based on the 100 -percent data collected at the time of each census, 1900 to 2000. The age data, and calculations based on these data, generally were derived based on the distribution of the population in 5 -year age groups.
For the total population, the only use of sample data concerned the derivation of the population ages 75 to 79 years and 80 to 84 years in 1950. The published 100 -percent data on age provided only a total for the age group 75 to 84 years. Totals for the two 5 -year age groups consistent with the 100 -percent total of 75 -to84 -year olds were obtained through proration. The proportions of people age 75 to 79 years and 80 to 84 years of the population age 75 to 84 from sample data totals for the age groups were applied to the population age 75 to 84 years from the 100 -percent data.
In general, the 100 -percent data tabulations of age by race were used to calculate median age by race. Age measures for the Black population in 1950 and 1960 and for the American Indian and Alaska Native and the Asian and Pacific Islander populations in 1950, 1960, and 1970 were based on sample data (see Appendix Table 11).

## RACE AND HISPANIC ORIGIN DATA

## Race

Data on race have been collected since the first U.S. decennial census in 1790. The terms used to describe each race, the categories collected on the questionnaire,
the method of obtaining responses on race, and the manner of tabulating the data all changed over the course of the 20th century. These changes create some comparability issues with regard to the interpretation and understanding of historical tabulations of data by race. ${ }^{3}$
The race data included in this report represent the totals as reported at the time of each census, with one exception. The 1930 census included a separate race category for the Mexican population, while the 1940 census eliminated this category and revised the 1930 data tabulation to include the Mexican population in the White population. For increased comparability, this report uses the 1940 revision of the 1930 race data.
Prior to 1950, all published race data could be classified into one of four categories: White, Black, Asian and Pacific Islander, and American Indian, Eskimo, and Aleut. Beginning with the 1950 census, the category "Other" or "Some other race" became a fifth major category. For Census 2000, the Asian and Pacific Islander category was split into "Asian" and "Native Hawaiian and Other Pacific Islander." Also, for the first time, individuals could identify themselves or other members of their household as more than one race. As a result, a seventh major category, "Two or more races," was added to allow for the tabulation of people who reported more than one of the six major categories.
Although the collection of race data for specific population groups varied over the censuses, this report discusses population and housing trends prior to 1950 for the four categories mentioned above, includes the Some other race category from 1950 through 2000, and highlights the Two or more races category for Census 2000. So, for example, although the collection of data classifying the Eskimo, Aleut, or Alaska Native population category separately did not occur in all states until the 1980 census, this report uses the Census 2000 term, "American Indian and Alaska Native" for the period 1900 to 2000.
Another data comparability issue concerns the introduction of the "Other race" category in the 1950 census, when Asian groups other than Chinese and Japanese were classified in the "Other" category. Data on the total number of Filipinos in the United States in 1950 $(61,636)$ were provided in a special report that showed

[^75]the number of Filipinos by state for those states with a Filipino population of at least 2,500 (California, Washington, and New York, see Gibson and Jung, 2002). For the purposes of this report, the Filipino population in 1950 is included in the "Other race" population for states, regions, and the United States.
Since Census 2000 allowed individuals to self-identify as more than one race for the first time, the data on race may be divided into two broad categories: the race alone population and the race in combination population. People who indicated only one race are referred to as the race alone population. Individuals who chose more than one of the six individual race categories are referred to as the race in combination population, or as the group who reported more than one race. Adding the race alone population and the race in combination population together creates the maximum number of people reporting an individual race, and is referred to as the race alone or in combination population.
All of the people reporting more than one of the six race categories collectively are termed the Two or more races population. For graphs shown in this report, Census 2000 data by race generally pertain to the race alone population for the individual races, with a separate value shown for the Two or more races population. Some graphs provide both the race alone and the race alone or in combination data. The use of one population or the other does not imply any preferred method of presenting or analyzing the data. In general, either population may be used, depending on the purpose of the analysis. The Census Bureau uses both approaches. The detailed tables provide both sets of data.
Although the 1990 race category, Asians and Pacific Islanders was split into "Asian" and "Native Hawaiian and Other Pacific Islander" in Census 2000, this report uses the single 1990 designation to maximize comparability throughout the century. People who reported as the specific two race combination Asian and Native Hawaiian and Other Pacific Islander in Census 2000 are included in the Two or more races category.

## Hispanic Origin

Race and Hispanic origin are treated as two separate concepts. People of Hispanic or Latino origin may be of any race, and conversely, people of each race may be either Hispanic or not Hispanic.
The 1970 census was the first to include a separate question specifically on Hispanic origin, although it was only asked of a 5 -percent sample of households. ${ }^{4}$ Prior to 1970, Hispanic origin was determined only indirectly. For example, the 1950 and 1960 censuses
tabulated data for "persons of Spanish surname" only in Arizona, California, Colorado, New Mexico, and Texas. As noted above, Mexican was included as a category within the question on race in the 1930 census.
Data trends on the Hispanic population in this report cover the period 1980 to 2000, corresponding to the census years for which data on Hispanics were obtained on a 100 -percent basis.

## Minority Population

For the period 1980 to 2000, the term Minority population is used in this report to refer to the aggregated number of all people who are of races other than White or who are Hispanic. Examining the demographic trends for this combined population group broadly illustrates the diversity of the U.S. population. Furthermore, including an aggregated Minority population group in several graphics permits an overall comparison with its complement, the White nonHispanic population.

## HOUSING DATA

The 1900 through the 1930 population censuses collected limited information on the number of occupied housing units in the United States. These censuses did not collect data on the number of vacant units and other detailed characteristics of housing units. The first Census of Housing was conducted in 1940, providing more detailed information on the characteristics of housing units. Information on occupancy status (occupied or vacant) has been collected on a 100 -percent basis since 1940. Housing tenure data (owner occupied or renter occupied) have been available throughout the century, although the population censuses of 1900 to 1930 include a number of occupied housing units with tenure status not known. Many other characteristics of housing units were collected in Census 2000, but only on a sample-basis, and thus are not within the scope of this report.
The discussion of overall housing tenure trends, including owner-occupied housing, renter-occupied housing, and rates of homeownership (percent owneroccupied housing of all occupied units) covers the period 1900 to 2000. Homeownership rates by other population characteristics of the householder are only available for more recent decades from the census of housing. Similarly, since the population censuses of 1900 to 1930 did not include information on the number of vacant housing units, the discussion of

[^76]trends in the total number of housing units and the percent vacant (or percent occupied) of all housing units is limited to the period 1940 to 2000.

## HOUSEHOLD DATA

Data on the number and size of households, types of households, and household characteristics were obtained from both the population and the housing censuses. In some cases, data on household characteristics available on a 100-percent basis from Census 2000 were only available on a sample basis from earlier censuses. In such cases, the data have been identified in italics in the detailed tables.

## Household Size

Information on the total number of households by size of household is not available for every census, 1900 to 2000. This occurred because the definition and/or concept of what constituted a household varied somewhat over the course of the century. In particular, the population censuses of 1910 and 1920 included a small number of "quasi-households," which, in Census 2000 terms would often have been considered as part of the group quarters population, rather than as part of the household population. The 1930 census similarly does not report the distribution of households by size, excluding the quasi-household population. Thus, these data are not strictly comparable with data for other years and were not included in the discussion of household trends.

The 1900 census of population showed a distribution of households from 1 to 7 or more people that included group quarters facilities. The distribution of households by size for 1900 shown in this report assumes that all group quarters facilities had at least seven people. Thus, the reported number of households with 1 to 6 people was accepted and the number of households with 7 or more people $(3,059,095)$ used in this report was derived by subtracting the number of group quarters facilities $(223,750)$ from the reported number of households plus group quarters facilities with 7 or more people $(3,282,845)$.

## Household Type

Family and nonfamily households represent the broadest categories of household type used in census data tabulations. This report mainly discusses trends for four major household types. They are comprised of two types of family households (married-couple households and other family households) and two types of nonfamily households (one-person households and other nonfamily households). The
report discusses some trends of family households using three categories: married-couple households, male householder with no wife present, and female householder with no husband present.
Only population and housing census data from 1950 to 2000 allowed for the derivation of comparable data trends by type of household. Even some of these data required minor modifications from their originally published form. Also, in several cases, tabulations based on 100-percent data were not available. In such cases, available sample data tabulations were incorporated. Numbers based on sample data are indicated as such using italics in the detailed tables.

Tabulations of the 1950 and 1960 censuses by household type, in particular, required relying on data collected from a sample of U.S. households. Documentation from these censuses generally notes that sample household results by type slightly overrepresent family households and thus underrepresent nonfamily households.

Since 1970, the number of family households by definition equals the total number of families. In the 1950 and 1960 censuses, it was possible for households to contain more than one family. The term "primary family" generally represented the family concept as used in censuses since 1970. To increase comparability, the tabulated data on all families from the 1950 census were modified to show primary families only.

The data on one-person households in several censuses frequently were only published as part of the housing census. In such cases, the number of other nonfamily households was derived as a residual of total nonfamily households from the population census minus one-person households from the housing census tabulations.

## Household Characteristics

This report discusses trends in the characteristics of households as defined by the age, sex, race, and Hispanic origin of the householder. The characteristic of the household thus is determined by the characteristic of the householder. In addition, this report describes the trends in families by the presence and ages of own children.

As was true for household type, data availability and comparability permitted the examination of household characteristics trends only since 1950. Also, some data could be obtained only from sample tabulations, particularly data from the 1950 and 1960 censuses.

[^0]:    Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

[^1]:    See U.S. Census Bureau, 2001g, Population Change and Distribution: 1990 to 2000, by Marc J. Perry and Paul J. Mackun. Population change in any decade may result from changes in census coverage, as well as from births, deaths, and net international migration.
    ${ }^{2}$ The higher percentage increase results because the total population base in 1900 ( 76.0 million) is much smaller than the population base in 1990 (248.7 million).

[^2]:    ${ }^{3}$ See U.S. Census Bureau, the International Data Base at www.census.gov/ipc/www/idbnew.html.

[^3]:    ${ }^{4}$ For the definition of more developed countries and less developed countries, see the Glossary.

[^4]:    ${ }^{6}$ See U.S. Census Bureau, 2000, Statistical Abstract of the United States: 2000 (120th edition), Washington, DC.

[^5]:    ${ }^{5}$ Density represents the average number of people per unit of land area (such as square miles, square kilometers). All density calculations for the United States, regions, and states in this report are based on land area measurement used for Census 2000.

[^6]:    7 The calculation of the mean center of population for 1900 through 1950 is based on the population of the conterminous United States and for 1960 through 2000 includes the populations of Alaska and Hawaii. Including Alaska and Hawaii in 1960 had the effect of shifting the mean center about 2 miles farther south and about 10 miles farther west.

[^7]:    ${ }^{8}$ Since the 1950 census, the U.S. Census Bureau has classified all states and the District of Columbia into one of four regionsNortheast, Midwest, South, and West. For the definition of each region by state, see the Glossary.

[^8]:    ${ }^{9}$ The District of Columbia, considered a state equivalent for statistical purposes, had less than 1 million residents for the entire century.
    ${ }^{10}$ The District of Columbia, with 572,059 residents in 2000 , had a smaller population than every state, except Wyoming.

[^9]:    Note: The District of Columbia is considered a state equivalent for statistical purposes.

[^10]:    ${ }^{11}$ The District of Columbia is usually considered a state equivalent for statistical purposes, and its density was higher by far than all 50 states throughout the century. However, it is excluded from the general discussion of state population density due to its lesser comparability attributable to a relatively small land area and its greater comparability to other cities, rather than states.
    ${ }^{12}$ State population density calculations in this report are based on land area measurement used for Census 2000.

[^11]:    ${ }^{13}$ The 1910 forerunner of a metropolitan area was the "metropolitan district." Metropolitan districts/areas were redefined at each census. The definition of metropolitan areas was based on county boundaries for the first time in 1950 (see the Glossary). Data presented in Figures 1-14 through 1-19 are based on the definition of metropolitan at the time of each census.

[^12]:    ${ }^{14}$ For the definitions of metropolitan, central city, and suburb, see the Glossary.

[^13]:    ${ }^{15}$ Metropolitan trends have been limited in most figures to censuses since 1950, when metropolitan areas based on county units were first defined.

[^14]:    Source: U.S. Census Bureau, decennial census of population, 1950 to 2000.

[^15]:    ${ }^{16}$ See U.S. Census Bureau. 1991. Metropolitan Areas and Cities. 1990 Census Profile, Number 3.
    ${ }^{17}$ Los Angeles-Riverside-Orange County, Washington-Baltimore, San Francisco-Oakland-San Jose, Philadelphia-Wilmington-Atlantic City, Boston-Worcester-Lawrence, Detroit-Ann Arbor-Flint, and DallasFort Worth.

[^16]:    ${ }^{18}$ Although metropolitan areas were first classified as such in 1950, clearly New York ranked first in metropolitan population throughout the entire century.

[^17]:    ${ }^{1}$ A small portion of the Philadelphia SCSA (1980) and CMSA (1990 and 2000) includes population in states of the South region (Delaware and Maryland).

[^18]:    ${ }^{19}$ The relative stability of nonmetropolitan density occurred even though the nonmetropolitan population was smaller in 2000 than in 1950. A corresponding decline in the total area of nonmetropolitan territory partially offset the drop in population.

[^19]:    ${ }^{20}$ The density levels for suburban areas shown in Figure 1-17 should be interpreted with caution. Suburban population as used in this report refers to the population living in metropolitan areas, outside central cities. Using this definition includes a nontrivial portion of county land area that is predominantly rural. This produces lower density levels than would result if suburban were defined by using the population living in the "urban fringe" of urbanized areas.

[^20]:    ${ }^{21}$ The District of Columbia is usually considered a state equivalent for statistical purposes, and its percentage metropolitan was 100 percent in every census from 1910 to 2000. However, it is excluded from the general discussion of the percentage metropolitan by state due to its particularly greater comparability to other cities, rather than states, on this population measure.

[^21]:    ${ }^{22}$ See U.S. Census Bureau. 2001a. Age: 2000, by Julie Meyer.

[^22]:    Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

[^23]:    ${ }^{23}$ This method standardizes (to 100 percent) the total area of each pyramid. In this representation, the shape of the pyramid is more useful than the length of each bar when making pyramid-to-pyramid comparisons.

[^24]:    ${ }^{24}$ The median age is the age that divides the population into two equal-size groups. Half of the population is older than the median age and the other half is younger. See the Glossary.

[^25]:    Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

[^26]:    ${ }^{25}$ In this report, the term elderly refers to individuals aged 65 years and over.
    ${ }^{26}$ See U.S. Census Bureau. 2001h. The 65 Years and Over Population, by Lisa Hetzel and Annetta Smith.

[^27]:    Source: U.S. Census Bureau, decennial census of population, 1900, 1950, and 2000.

[^28]:    ${ }^{28}$ Calculated as the male population divided by the female population, times 100. See the Glossary.

[^29]:    ${ }^{29}$ Differences in census coverage also affect the sex ratio. In the United States, men generally have been less completely counted than women. This implies that the census-based sex ratio is slightly lower than if all people had been completely counted (see J. Gregory Robinson, "Accuracy and Coverage Evaluation: Demographic Analysis Results," March 12, 2001.)

[^30]:    Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

[^31]:    ${ }^{30}$ See U.S. Census Bureau. 2001b. Gender: 2000, by Denise I. Smith and Reneé E. Spraggins.

[^32]:    ${ }^{31}$ The District of Columbia, a state equivalent for statistical purposes, had the lowest sex ratio for every decade throughout the century.

[^33]:    ${ }^{32}$ Metropolitan areas were formally defined beginning with the 1950 census.

[^34]:    ${ }^{33}$ In 1999, average life expectancy at birth (based on age-specific mortality rates in 1999) was 73.9 years for males and 79.4 years for females. See U.S. National Center for Health Statistics, 2002, United States Life Tables, 1999, Table A.

[^35]:    ${ }^{34}$ In Census 2000, the Asian and Pacific Islander group was split into "Asian" and "Native Hawaiian and Other Pacific Islander." For comparability throughout the century, this report combines these two groups. Separate data for each group from Census 2000 are provided in Appendix Table 9.

[^36]:    ${ }^{35}$ In Figure 3-3 and all following graphics including a percentage of the population for a specific race group, the percentage shown for Census 2000 is based on the number of people reporting the specified race alone rather than the number reporting the specified race alone or in combination with any other race. The use of the race alone concept does not imply that it is a preferred method of presenting or analyzing data. In general, either the alone population or the alone or in combination population can be used, depending on the purpose of the analysis. The Census Bureau uses both approaches. See U.S. Census Bureau, 2001f, Overview of Race and Hispanic Origin, by Elizabeth M. Grieco and Rachel C. Cassidy.

[^37]:    Note: In 2000, the percents are based on the reporting of the specified race alone.
    Source: U.S. Census Bureau, decennial census of population, 1900 to 2000.

[^38]:    ${ }^{36}$ For a more detailed discussion about race and Hispanic origin, see the Sources and Quality of Data section.
    ${ }^{37}$ The 1970 census included a question on the Hispanic origin of individuals asked of a 5-percent sample. In this report, data on Hispanic origin are shown from 1980 to 2000.

[^39]:    ${ }^{38}$ Since the write-in responses to race prior to 1950 were tabulated as specific races and were classifiable into one of the four specific race groups, no fifth other race category is applicable for these censuses. As a result, growth rates are not available for this classification for the 1900-1950 and 1900-2000 periods shown in Figure 3-6.

[^40]:    ${ }^{39}$ See U.S. Census Bureau. 2001 f. Overview of Race and Hispanic Origin, by Elizabeth M. Grieco and Rachel C. Cassidy.

[^41]:    ${ }^{41}$ In this report, the Minority population refers to the aggregate number of people who are races other than White (and other than White alone for Census 2000) or who are Hispanic.

[^42]:    ${ }^{42}$ In addition to West Virginia, the percentage of races other than White was also higher in 1950 than in 1900 in the District of Columbia, considered a state equivalent for statistical purposes and also part of the U.S. Census Bureau's South region.

[^43]:    ${ }^{44}$ See U.S. Census Bureau. 2001i. The Two or More Races Population: 2000, by Nicholas A. Jones and Amy Symens Smith.

[^44]:    ${ }^{46}$ The aggregate Minority population as shown in this report represents people who are races other than White (and other than White alone for Census 2000) or who are Hispanic. For more details, see the Sources and Quality of Data section and the Glossary.

[^45]:    ${ }^{47}$ For further discussion of the history of population data on the American Indian and Alaska Native population, see C. Matthew Snipp, 2000, "American Indians and Alaska Natives," Encyclopedia of the U.S. Census, Margo J. Anderson (ed.).

[^46]:    ${ }^{48}$ See the Glossary for the definition of a housing unit.

[^47]:    ${ }^{49}$ Census 2000 subdivided vacant housing units into six housing market classifications: for rent; for sale only; rented or sold, not occupied; for seasonal, recreational, or occasional use; for migrant workers; and other vacant.

[^48]:    ${ }^{50}$ See the Glossary for definitions of metropolitan areas, nonmetropolitan areas, suburbs, and central cities.
