

United States Life Tables, 2004

by Elizabeth Arias, Ph.D., Division of Vital Statistics

Abstract

This report presents period life tables for the United States based on age-specific death rates in 2004. Data used to prepare these life tables are 2004 final mortality statistics; July 1, 2004, population estimates based on the 2000 decennial census and data from the Medicare program. Presented are complete life tables by age, race, and sex. In 2004, the overall expectation of life at birth was 77.8 years, representing an increase of 0.4 year from life expectancy in 2003. Between 2003 and 2004, life expectancy increased for males and females, and for both the white and black populations. Life expectancy increased by 0.5 years (from 72.6 to 73.1) for the black population and by 0.4 year (from 77.9 to 78.3) for the white population. Both males and females in each race group experienced increases in life expectancy between 2003 and 2004. The greatest increase was experienced by black males with an increase of 0.6 year (from 68.9 to 69.5). Life expectancy increased by 0.4 year for black females (from 75.9 to 76.3), for white females (from 80.4 to 80.8), and for white males (from 75.3 to 75.7).

Introduction

There are two types of life tables—the cohort (or generation) life table and the period (or current) life table. The cohort life table presents the mortality experience of a particular birth cohort, all persons born in the year 1900, for example, from the moment of birth through consecutive ages in successive calendar years. Based on age-specific death rates observed through consecutive calendar years, the cohort life table reflects the mortality experience of an actual cohort from birth until no lives remain in the group. To prepare just a single complete cohort life table requires data over many years. It is usually not feasible to construct cohort life tables entirely on the basis of observed data for real cohorts due to data unavailability or incompleteness (1). For example, a life table representation of the mortality experience of a cohort of persons born in 1970 would require the use of data projection techniques to estimate deaths into the future (2,3).

Unlike the cohort life table, the period life table does not represent the mortality experience of an actual birth cohort. Rather, the period life table presents what would happen to a hypothetical (or synthetic) cohort if it experienced throughout its entire life the mortality conditions of a particular period in time. Thus, for example, a period life table for 2004 assumes a hypothetical cohort subject throughout its lifetime to the age-specific death rates prevailing for the actual population in 2004. The period life table may thus be characterized as rendering a “snapshot” of current mortality experience, and shows the long-range implications of a set of age-specific death rates that prevailed in a given year. In this report, the term “life table” refers only to the period life table and not to the cohort life table.

Data and Methods

The data used to prepare the U.S. life tables for 2004 are final numbers of deaths for the year 2004, postcensal population estimates for the year 2004, and data from the Medicare program of the Centers for Medicare and Medicaid Services.

The populations used to estimate the life tables shown in this report were produced under a collaborative agreement with the U.S. Census Bureau and are consistent with the postcensal estimates of the 2000 census. Reflecting the new guidelines issued in 1997 by the Office

Acknowledgments

This report was prepared in the Division of Vital Statistics (DVS) under the general direction of Charles J. Rothwell, Director of DVS and Robert N. Anderson, Chief of the Mortality Statistics Branch (MSB). Content review was provided by Betzaida Tejada-Vera of MSB and Vanetta Harrington of the Systems, Programming, and Statistical Resources Branch (SPSRB). Bonita Gross and David P. Johnson of SPSRB prepared the mortality file. Registration and Methods staff and staff of the Data Acquisition and Evaluation Branch provided consultation to state vital statistics offices regarding collection of the death certificate data on which this report is based. This report was edited by Demarius V. Miller, CDC/CCHIS/NCHM/Division of Creative Services, Writer-Editor Services Branch; typeset by Jacqueline M. Davis, CDC/CCHIS/NCHM/Division of Creative Services; and graphics produced by Jarmila G. Ogburn, CDC/CCHIS/NCHM/Division of Creative Services.

Keywords: life expectancy • life tables • survival • death rates • race

of Management and Budget (OMB), the 2000 census included an option for individuals to report more than one race as appropriate for themselves and household members (4). The 1997 OMB guidelines also provided for the reporting of Asian persons separately from Native Hawaiian or other Pacific Islanders. Under the prior OMB standards (issued in 1977), data for Asian or Pacific Islander persons were collected as a single group (5). Beginning with deaths occurring in 2003, some states implemented multiple-race categories on the death certificate. Most states continue to collect only one race for the decedent in the same categories as specified in the 1977 OMB guidelines (death certificate data do not report Asians separately from Native Hawaiian or other Pacific Islanders). Death certificate data by race for these states (the numerators for death rates) are thus currently incompatible with the population data collected in the 2000 census (the denominators for the rates). To produce death rates for 2000–2004 it was necessary to “bridge” the reported population data for multiple-race persons back to single-race categories. In addition, the 2000 census counts were modified to be consistent with the 1977 OMB race categories, that is, to report the data for Asian persons and Native Hawaiian or other Pacific Islanders as a combined category, Asian or Pacific Islander, and to reflect age as of the census reference data (6). The procedures used to produce the “bridged” populations are described in separate publications (7). It is anticipated that “bridged” population data will be used over the next few years for computing population-based rates. Multiple-race data for those states that implemented the 1997 OMB guidelines in 2003 are bridged back to single race categories. Once all states are collecting data on race according to the 1997 OMB guidelines, it is expected that use of the bridged populations will be discontinued.

Readers should keep in mind that the population data used to compile death rates by race are based on special estimation procedures. They are not true counts. This is the case even for the 2000 populations that are based on the 2000 census. The estimation procedures used to develop these populations contain some error (7). Over the next several years, additional information will be incorporated in the estimation procedures, possibly resulting in further revisions of the population estimates (see “[Technical Notes](#)”).

Data from the Medicare program are used to calculate probabilities of dying for ages greater than 84 years (see “[Technical Notes](#)”).

Life tables can be classified in two ways according to the length of the age interval in which data are presented. A complete life table contains data for every single year of age. An abridged life table typically contains data by 5- or 10-year age intervals. A complete life table, of course, can be easily aggregated into 5- or 10-year age groups (see “[Technical Notes](#)” for instructions on how to do this). Other than the decennial life tables, U.S. life tables based on data prior to 1997 are abridged life tables constructed by reference to a standard table (8). The 2004 U.S. life tables are complete life tables calculated using a method implemented with the 1997 life tables and are similar to the U.S. Decennial Life Tables (9,10). See “[Technical Notes](#)” for more information on the method used to construct the life tables in this report.

Expectation of life—The most frequently used life table statistic is life expectancy (e_x), which is the average number of years of life remaining for persons who have attained a given age (x). Life expectancy and other life table values for each age in 2004 are shown for the total population and by race and sex in [tables 1–9](#). Life expectancy is summarized by age, race, and sex in [Table A](#).

Life expectancy at birth (e_0) for 2004 for the total population was 77.8 years. This represents the average number of years that the members of the hypothetical life table cohort may expect to live at the time of birth ([Table A](#)).

Survivors to specified ages—Another way of assessing the longevity of the synthetic life table cohort is by determining the proportion who survive to specified ages. The l_x column of the life table provides the data for computing the proportion. [Table B](#) summarizes the number of survivors by age, race, and sex. To illustrate, 53,925 persons out of the original 2004 synthetic life table cohort of 100,000 (or 53.9 percent) were alive at exact age 80. In other words, the probability that a person will survive from birth to age 80, given 2004 age-specific mortality, is 54 percent. Probabilities of survival can be calculated at any age by simply dividing the number of survivors at the terminal age by the number at the beginning age. For example, to calculate the probability of surviving from age 20 to age 85, one would divide the number of survivors at age 85 (38,329) by the number of survivors at age 20 (98,709), which results in a 38.8 percent probability of survival.

Explanation of the columns of the life table

Column 1—(x to $x + 1$)—This column shows the age interval between the two exact ages indicated. For instance, “20–21” means the 1-year interval between the 20th and 21st birthdays.

Column 2—Probability of dying (q_x)—This column shows the probability of dying between ages x to $x + 1$. For example, for males in the age interval 20–21 years, the probability of dying is 0.001266 ([Table 2](#)). The “probability of dying” column forms the basis of the life table; all subsequent columns are derived from it.

Column 3—Number surviving (l_x)—This column shows the number of persons from the original synthetic cohort of 100,000 live births, who survive to the beginning of each age interval. The l_x values are computed from the q_x values, which are successively applied to the remainder of the original 100,000 persons still alive at the beginning of each age interval. Thus, out of 100,000 female babies born alive, 99,391 will complete the first year of life and enter the second; 99,218 will reach age 10; 98,944 will reach age 20; and 45,438 will live to age 85 ([Table 3](#)).

Column 4—Number dying (d_x)—This column shows the number dying in each successive age interval out of the original 100,000 live births. For example, out of 100,000 males born alive, 747 will die in the first year of life; 125 between ages 20 and 21; and 1,261 will die after reaching age 100 ([Table 2](#)). Each figure in column 4 is the difference between two successive figures in column 3.

Column 5—Person-years lived (L_x)—This column shows the number of person-years lived by the synthetic life table cohort within an age interval x to $x + 1$. Each figure in column 5 represents the total time (in years) lived between two indicated birthdays by all those reaching the earlier birthday. Thus, the figure 98,424 for males in the age interval 20–21 years is the total number of years lived between the 20th and 21st birthdays by the 98,486 (column 3) males who reached their 20th birthday out of 100,000 males born alive ([Table 2](#)).

Column 6—Total number of person-years lived (T_x)—This column shows the total number of person-years that would be lived after the beginning of the age interval x to $x + 1$ by the synthetic life table cohort.

Table A. Expectation of life by age, race, and sex: United States, 2004

Age	All races			White			Black		
	Total	Male	Female	Total	Male	Female	Total	Male	Female
0	77.8	75.2	80.4	78.3	75.7	80.8	73.1	69.5	76.3

50	30.9	28.8	32.7	31.1	29.1	32.9	27.8	25.1	30.1
55	26.6	24.7	28.3	26.7	24.9	28.4	24.0	21.5	26.0
60	22.5	20.8	24.0	22.6	20.9	24.1	20.4	18.2	22.2
65	18.7	17.1	20.0	18.7	17.2	20.0	17.1	15.2	18.6
70	15.1	13.7	16.2	15.1	13.7	16.2	14.1	12.4	15.3
75	11.9	10.7	12.8	11.9	10.7	12.8	11.4	9.9	12.2
80	9.1	8.2	9.8	9.1	8.1	9.7	9.1	8.0	9.6
85	6.8	6.1	7.2	6.7	6.0	7.1	7.1	6.3	7.5
90	5.0	4.4	5.2	4.9	4.3	5.1	5.5	4.9	5.7
95	3.6	3.2	3.7	3.5	3.1	3.6	4.2	3.8	4.3
100	2.6	2.3	2.6	2.5	2.2	2.5	3.2	2.9	3.2

For example, the figure 5,537,328 is the total number of years lived after attaining age 20 by the 98,486 males reaching that age (Table 2).

Column 7—Expectation of life (e_x)—The expectation of life at any given age is the average number of years remaining to be lived by those surviving to that age on the basis of a given set of age-specific rates of dying. It is derived by dividing the total person-years that would be lived above age x by the number of persons who survived to that age interval (T_x / I_x). Thus, the average remaining lifetime for males who reach age 20 is 56.2 years (5,537,328 divided by 98,486) (Table 2).

Results

Life expectancy in the United States

Tables 1–9 show complete life tables by race (white and black) and sex for 2004. Tables A and B summarize life expectancy and survival by age, race, and sex. Life expectancy at birth for 2004 represents the average number of years that a group of infants would live if the infants were to experience throughout life the age-specific

death rates prevailing in 2004. In 2004, life expectancy at birth was 77.8 years, increasing by 0.4 year from 77.4 years in 2003. [The 2003 U.S. life tables figures presented in this report are revised estimates. The original "United States Life Tables, 2003" report, published in April 2006 contained an error. A copy of the revised report is available from: http://www.cdc.gov/nchs/data/nvsr/nvsr54/nvsr54_14.pdf]. This increase is typical of the average yearly changes that occurred during the last 30 years in the United States. Throughout the past century, the trend in U.S. life expectancy was one of gradual improvement that has continued into the new century (11).

Life expectancy in 2004 was 75.2 years for males, increasing by 0.5 year from 74.7 years in 2003. Life expectancy for females was 80.4 years, increasing by 0.4 year from 80.0 years in 2003. The increase in life expectancy between 2003 and 2004 for females was primarily the result of decreases in mortality from diseases of heart, malignant neoplasms, cerebrovascular diseases, chronic lower respiratory diseases, and pneumonia. The increase in life expectancy for females could have been greater than 0.4 year were it not for the offsetting effect of increases in mortality from accidents, suicide, Alzheimer's disease, and maternal conditions. For males, life expectancy increased primarily because of decreases in mortality from diseases of heart, malignant neoplasms, cerebrovascular diseases, chronic lower respiratory diseases, and pneumonia. The increase in life expectancy for males could have been greater than 0.5 year were it not for the offsetting increases in mortality from accidents, hypertension, and suicide (12).

The difference in life expectancy between the sexes was 5.2 years in 2004, down by 0.1 year from 2003. From 1900 to 1975, the difference in life expectancy between the sexes increased from 2.0 years to 7.8 years. The increasing gap during these years is attributed to increases in male mortality due to ischemic heart disease and lung cancer, both of which increased largely as the result of men's early and widespread adoption of cigarette smoking (11,13). Since 1979, the difference in life expectancy between the sexes has narrowed from 7.8 years to 5.2 years, reflecting proportionately greater increases in lung cancer mortality for women than for men and proportionately larger decreases in heart disease mortality among men (11,13).

Between 2003 and 2004, life expectancy for the black population rose 0.5 year to 73.1 years. For the white population, life expectancy rose by 0.4 year to 78.3 years. The difference in life expectancy between the white and black populations was 5.2 years in 2004, a historically record low level. The white-black difference in life expectancy narrowed from 14.6 years in 1900 to 5.7 years in 1982, but increased to 7.1 years in 1993 before beginning to decline again in 1994 (7.0 years). The increase in the gap from 1983 to 1993 was largely the result of increases in mortality among the black male population due to HIV infection and homicide (11,14).

Among the four race-sex groups (Figure 1), white females continued to have the highest life expectancy at birth (80.8 years), followed by black females (76.3 years), white males (75.7 years), and black males (69.5 years). Between 2003 and 2004, life expectancy increased 0.6 year for black males (from 68.9 in 2003 to 69.5 in 2004). Black males experienced an unprecedented decline in life expectancy every year for 1984–1989 (14), but annual increases in 1990–1992 and 1994–2004. From 2003 to 2004, life expectancy for black females increased from 75.9 years to 76.3 years, an increase of 0.4 year. Life expectancy for white males rose 0.4 year, from 75.3 years in 2003 to

Figure 1. Life expectancy at birth, by race and sex: 1970–2004

75.7 years in 2004. White female life expectancy increased during the same period by 0.4 year from 80.4 to 80.8 years. Overall, gains in life expectancy between 1980 and 2004 were 5.7 years for black males, 5.0 years for white males, 3.8 years for black females, and 2.7 years for white females (Table 12).

The 2004 life table may be used to compare life expectancy at any age from birth onward. On the basis of mortality experienced in 2004, a person aged 65 years could expect to live an average of 18.7 more years for a total of 83.7 years, and a person aged 100 years could expect to live an additional 2.6 years on average (Table A). Life expectancy at 100 years of age, particularly for the black population, should be interpreted with caution as these figures may be affected somewhat by age misreporting (9,15,16).

Survivorship in the United States

Table B summarizes the number of survivors out of 100,000 persons born alive (l_x) by age, race, and sex. Table 10 shows trends in survivorship from 1900 to 2004. In 2004, 99.3 percent of all infants born in the United States survived the first year of life. In contrast, only 87.6 percent of infants born in 1900 survived the first year. Fifty-four percent of the 2004 synthetic life table cohort survived to age 80 and about 2.5 percent survived to age 100. In 1900, the median age at death was 58 years and only 0.03 percent survived to age 100.

Among the four race-sex groups (Figure 2 and Table B), white females have the highest median age at death with about 49.6 percent

Figure 2. Percentage surviving by age, race, and sex: United States, 2004

surviving to age 84. Of the original hypothetical cohort of 100,000 infant white females, 99.1 percent survive to age 20, 87.9 percent survive to age 65, and 46.2 percent survive to age 85. For white males and black females, the pattern of survival by age is similar. These groups have approximately the same median age at death of about 80 years. However, white males have slightly higher survival rates than black females at the younger ages with 98.7 percent surviving to age 20 and 80.5 percent surviving to age 65 compared with 98.2 percent and 79.2 percent, respectively, for black females. At the older ages, in contrast, black female survival surpasses white male survival. At age 85, white male survival is 31.3 percent compared with 35.6 percent for black females. This crossover, which occurs at about age 74, is clearly shown in Figure 2. The median age at death for black males is 73 years, 11 years less than that for white females. 97.4 percent of black males survive to age 20, 66.8 percent to age 65, and 20.0 percent to age 85. By age 100, there is very little difference between the white and black populations in terms of survival. Approximately 1 percent of white and black males and 3 percent of white and black females, respectively, survive to age 100.

Plotting the percentage surviving by age for the periods 1900–1902, 1949–1951, and 2004 shows an increasingly rectangular survival curve (Figure 3). That is, the survival curve has become increasingly flat in response to progressively lower mortality, particularly at the younger ages, and increasingly vertical at the older ages. The survival curve for 1900–1902 shows a rapid decline in survival in the first few years of life and a relatively steady decline thereafter. In contrast, the survival curve for 2004 is nearly flat until about age 50 after which the decline in survival becomes more rapid. Improvements in survival between 1900–1902 and 1949–1951 occurred at all ages, although the largest improvements were among the younger population. Between 1949–1951 and 2004, improvements occurred primarily for the older population.

Figure 3. Percentage surviving by age: Death-registration states, 1900–1902, United States, 1949–1951, and 2004

List of Detailed Tables

1. Life table for the total population: United States, 2004	8
2. Life table for males: United States, 2004	10
3. Life table for females: United States, 2004	12
4. Life table for the white population: United States, 2004.	14
5. Life table for white males: United States, 2004	16
6. Life table for white females: United States, 2004	18
7. Life table for the black population: United States, 2004.	20
8. Life table for black males: United States, 2004	22
9. Life table for black females: United States, 2004	24
10. Survivorship by age, race, and sex: Death-registration states, 1900–1902 to 1919–1921, and United States, 1929–1931 to 2004	26
11. Life Expectancy by age, race, and sex: Death-registration states, 1900–1902 to 1919–1921, and United States, 1929–1931 to 2004	30
12. Estimated life expectancy at birth in years, by race and sex: Death-registration states, 1900–1928, and United States, 1929–2004	34

Table 1. Life table for the total population: United States, 2004

Age	Probability of dying between ages x to $x+1$	Number surviving to age x	Number dying between ages x to $x+1$	Person-years lived between ages x to $x+1$	Total number of person-years lived above age x	Expectation of life at age x

Table 10. Survivorship by age, race, and sex: Death-registration states, 1900–1902 to 1919–1921, and United States, 1929–1931 to 2004

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929–1931, data are for groups of registration states as follows: 1900–1902 and 1909–1911, 10 states and the District of Columbia (D.C.); 1919–1921, 34 states and D.C. Beginning 1970 excludes deaths of nonresidents of the United States; see "Technical Notes"]

Table 10. Survivorship by age, race, and sex: Death-registration states, 1900–1902 to 1919–1921, and United States, 1929–1931 to 2004—Con.

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929–1931, data are for groups of registration states as follows: 1900–1902 and 1909–1911, 10 states and the District of Columbia (D.C.); 1919–1921, 34 states and D.C. Beginning 1970 excludes deaths of nonresidents of the United States; see "Technical Notes"]

¹For 1939–1941 and 1949–1951, data shown are for the entire nonwhite population. During these periods, life tables were not constructed for the black population. See "Technical Notes."

Table 11. Life expectancy by age, race, and sex: Death-registration states, 1900–1902 to 1919–1921, and United States, 1929–1931 to 2004

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929–1931, data are for groups of registration states as follows: 1900–1902 and 1909–1911, 10 states and the District of Columbia (D.C.); 1919–1921, 34 states and D.C. Beginning 1970 excludes deaths of nonresidents of the United States; see "Technical Notes"]

¹Prior to 1970, data for the black population are not available. Data shown for 1900–1969 are for the nonwhite population. See "Technical Notes."²Alaska included in 1959 and Hawaii in 1960.³Estimates for 2003 have been revised. The revised U.S. Life Tables are available from: http://www.cdc.gov/nchs/data/nvsr/nvsr54/nvsr54_14.pdf.⁴Deaths based on a 50-percent sample.⁵Figures by race exclude data for residents of New Jersey; see "Technical Notes."

Technical Notes

The life table program—Three series of complete life tables are prepared by the National Center for Health Statistics (NCHS) for the U.S. population—decennial, annual preliminary, and annual final. The U.S. decennial life tables are based on decennial census data and deaths for a 3-year period around the census year. Preliminary life tables are based on a substantial sample (approximately 90 percent) of death records. Estimates of life expectancy from the preliminary series are published annually. The annual final life tables (referred to in this section as annual life tables) are based on a complete count of all reported deaths.

Available since 1945, the annual life tables are based on deaths occurring during the calendar year and on midyear postcensal population estimates provided by the U.S. Census Bureau. From 1945 to 1996, the annual life tables were abridged life tables and were constructed by reference to a standard table (8). Beginning with 1997 mortality data, complete life tables are constructed using a new methodology (9,10). Also for 1997, life expectancy and other life table values were shown for ages 85 to 100 for the first time as part of the annual U.S. life tables. Previously, the annual life tables were closed at age 85. Extension of the oldest age interval was implemented by NCHS for several reasons: survival in the U.S. is such that over one-third of the population survives beyond age 85, improvements have occurred in age reporting at older ages, and high quality old-age mortality data are available from the Medicare program.

Geographic coverage—The geographic areas covered in life tables before 1929–1931 were limited to the death-registration areas. Life tables for 1900–1902 and 1909–1911 were constructed using mortality data from the 1900 death-registration states (10 states and the District of Columbia (D.C.)) and for 1919–1921 from the 1920 death-registration states (34 states and D.C.). The tables for 1929–1931 through 1958 cover the coterminous United States. Decennial life table values for the 3-year period 1959–1961 were derived from data that include both Alaska and Hawaii for each year (Tables 10 and 11). Data for each year shown in Table 12 include Alaska beginning in 1959 and Hawaii beginning in 1960. However, it is not believed that the inclusion of these two states materially affects life table values.

Revised life table values—Life table values for 1960–1969, 1970–1979, and 1980–1989 were constructed using the U.S. decennial life tables for 1959–1961, 1969–1971, and 1979–1981, respectively, as the standard tables. The life table values for years prior to 1989 appearing in this publication are based on revised intercensal estimates of the populations for those years. As a result, the life table values for these years may differ from the life table values for those years published in *Vital Statistics of the United States* for 1989 and earlier years. Life table values for 1991–1999 are based on postcensal population estimates of the population enumerated in the 1990 decennial census, whereas life table values for 2000–2004 are based on population estimates of the population enumerated in the 2000 decennial census. As a result, life expectancy values across the 1990s are not comparable to those estimated for 2000–2004. A comparison of life expectancy values for 2000 estimated alternately with 1990-based postcensal estimates of the 2000 population and population estimates based on the 2000 census revealed that life expectancy values estimated using the 2000 census population estimates were slightly higher throughout the entire age range (17). Revised life table values for

1991–1999 using the census 2000-based new intercensal population estimates will be estimated by NCHS in the upcoming year.

New Jersey data, 1962–1964—The life tables for 1962 and 1963 for the six population groups involving race do not include data from New Jersey, which omitted the item on race from its certificates of live birth, death, and fetal death in use at the beginning of 1962. The item was restored during the latter part of 1962. However, the certificate revision without this item was used for most of 1962 as well as for 1963. For computing vital rates, populations by age, race, and sex (excluding New Jersey) were estimated to obtain comparable denominators. Approximately 7 percent of the New Jersey death records for 1964 did not contain the race designation. When the records were being electronically processed for this state, the “race not stated” deaths were proportionally allocated to white or to black.

Nonresidents—Beginning in 1970, the deaths of nonresidents of the United States have been excluded from the life table statistics.

Estimation of life table functions—For some years, it was necessary to estimate life table functions for some race-sex groups. In tables 10 and 11, figures for the black population during the periods 1949–1951 and 1959–1961 were estimated using figures for the non-white population. Life table functions were also missing in tables 10 and 11 for race-sex groups for the periods from 1900–1902 to 1939–1941. Figures were missing for the following groups:

Years	Race and sex
1900–1902	Total white, total black
1909–1911	Total white, total black
1919–1921	Total, male, female, total white, total black
1929–1931	Total, male, female, total white, total black

These figures were estimated by weighted averages using population distributions as the weights. For example, life expectancy at age 20 for the total black population was estimated by a weighted average of black male and black female life expectancies at age 20, using as weights the population distribution by sex of the black population aged 20 years.

Annual life tables were initiated in 1945 for white males, white females, all other males, and all other females. The figures in Table 12 by race and sex for the following years were estimated using a procedure other than the abridged life table methodology (18).

Years	Race and sex
1900–1945	Total
1900–1947	Male
1900–1947	Female
1900–1950	White
1900–1944	White male
1900–1944	White female

Annual life table functions were not calculated for the black population prior to 1970. In Table 12, life expectancy for the black population for years prior to 1970 are estimated using figures for the total nonwhite population.

Population bases for computing life tables—Populations used for computing life tables shown in this report represent the population residing in the United States, enumerated as of April 1 for census years and estimated as of July 1 for all other years. Life tables for the United States for 2004 are estimated using postcensal estimates published in

2004 based on the 2000 census estimated as of July 1, 2004. Life tables for 2000 shown in this report have been recomputed, based on revised populations that are consistent with the 2000 census. These estimates were produced under a collaborative arrangement with the U.S. Census Bureau and are based on the 2000 census counts by age, race, and sex, modified to be consistent with the U.S. Office of Management and Budget racial categories as of 1977 and historical categories for death data (5). The modified procedures are described in detail elsewhere (7). Life tables previously published in annual reports of final data for 1991 to 1999 were based on postcensal population estimates derived from the 1990 census. The 1991–1999 life tables will be re-estimated using 2000 census based intercensal population estimates.

Medicare data—Death rates at the oldest ages based on Medicare data are known to be more accurate than those based on vital statistics and census data. Consequently, q_x values calculated for ages 85 to 99 are based on Medicare data collected by the Centers for Medicare and Medicaid Services. Medicare data were limited to the group insured for hospital insurance as age reporting is considered best among this group (10,15,16). For the 2004 life tables, pooled 1999–2001 Medicare data were used as 2004 data were not available in time for the preparation of this report.

Methodology

A more detailed treatment of the methodology used to calculate these life tables is contained in a separate report (9). Calculation of the complete life table is derived from the probability of death (q_x), which depends on the number of deaths (D_x) and the midyear population (P_x) for each single year of age (x) observed during the calendar year of interest.

Adjustment for deaths for which age was not reported—An adjustment must be made to account for the small proportion of deaths each year for which age is not reported. The number of deaths in each age category is adjusted proportionally to account for those with not-stated ages. The following factor is used to make the adjustment. This factor (F) is calculated for each race-sex group for which life tables are constructed.

$$F = \frac{D}{D^a} \tag{1}$$

where D is the total number of deaths and D^a is the total number of deaths for which age is stated. F is then applied by multiplying it times the number of deaths in each age group. Table I shows values for F by race and sex used to adjust the 2004 mortality data.

Interpolation of P_x and D_x —Anomalies, both random and those associated with reporting age at death, can be problematic when using vital statistics and census data by single years of age to estimate the probability of death (1). Graduation techniques are often used to eliminate these anomalies and to derive a smooth curve by age. Beer's ordinary minimized fifth difference formula is used to obtain smoothed values of P_x and D_x (see reference 1 for details on the application of Beer's method).

Calculation of q_0 — q_0 is calculated by using a birth cohort method employing a separation factor (f) defined as the proportion of infant deaths in year t occurring to infants born in the previous year ($t-1$). f can be calculated by categorizing infant deaths by date of birth. The probability of death in the first year is calculated as

Table I. Values for F used to adjust for not-stated age based on 2004 mortality data

Race and sex	Total deaths	Total deaths for which age was not stated	F
Total	2,397,615	346	1.00014433
Male	1,181,668	274	1.00023193
Female	1,215,947	72	1.00005922
White	2,056,643	269	1.00013081
Male	1,007,266	218	1.00021647
Female	1,049,377	51	1.00004860
Black	287,315	64	1.00022280
Male	145,970	46	1.00031523
Female	141,345	18	1.00012736

$$q_0 = \frac{D_0(1-f)}{B^t} + \frac{D_0 f}{B^{t-1}} \tag{2}$$

where D_0 is the number of infant deaths adjusted for not-reported age, and B^t and B^{t-1} are the numbers of births in years t and $t-1$, respectively. Table II shows separation factors and numbers of births by race and sex for 2003–2004.

Calculation of q_x for ages 1–84— q_x is calculated assuming that l_x (number of survivors at exact age x in the life table population) declines linearly between x and $x+1$ (i.e., that deaths between exact age x and $x+1$ occur on average at age $x+1/2$). This simplification is generally considered acceptable when age intervals are 1 year of age in length (1). Under this assumption, $l_x = L_x + 1/2 d_x$ where L_x is the average life table population at risk of dying between ages x and $x+1$ and d_x is the number of deaths occurring between age x and $x+1$. q_x is then

$$q_x = \frac{d_x}{l_x} = \frac{d_x}{L_x + \frac{1}{2} d_x}$$

One can make the same assumption for the observed population (i.e., that the observed population aged x at risk of dying at the beginning of the year (N_x) declines linearly between ages x and $x+1$). Under this assumption, $N_x = P_x + 1/2 D_x$ where P_x is the midyear population or average observed population at risk of dying between ages x and $x+1$ and D_x is the observed number of deaths occurring between ages x and $x+1$. q_x is calculated as

$$q_x = \frac{D_x}{N_x} = \frac{D_x}{P_x + \frac{1}{2} D_x} \tag{3}$$

For $x = 1$ to 84, D_x is the observed number of deaths adjusted for not-stated age and P_x is the observed population at risk of dying between ages x and $x + 1$.

Use of Medicare data at ages 85 to 99 years—There is ample evidence that the rate of increase in q_x declines above age 85 (9,16,19–21). The change in q_x for ages over 85 years can be expressed using the formula

$$q_x = q_{x-1} \cdot e^k \tag{4}$$

where k_x denotes the age-specific rate of mortality change with age (16,20). Solving for k_x gives

$$k_x = \ln(q_x) - \ln(q_{x-1}) \tag{5}$$

Table II. Births in 2003 and 2004, deaths in 2004 of infants born in 2003 and 2004, and separation factors by race and sex: United States

	Total			White			Black		
	Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
Births									
2003	4,089,950	2,093,535	1,996,415	3,225,848	1,652,146	1,573,702	599,847	305,207	294,640
2004	4,112,052	2,104,661	2,007,391	3,222,928	1,650,697	1,572,231	616,074	313,896	302,178
Deaths in 2004 of infants born in									
2003	3,397	1,918	1,479	2,191	1,229	962	1,032	585	447
2004	24,539	13,800	10,739	16,040	9,036	7,004	7,462	4,184	3,278
Separation factor (f)	0.122	0.122	0.121	0.120	0.120	0.121	0.122	0.123	0.120

Values for k_x are then obtained from the Medicare data. Table III shows values for k by age, race, and sex based on pooled 1991–2001 Medicare data. These data show clearly a declining rate of increase in q_x over age 85 years. These k_x values are then used to obtain q_x values for ages 85 to 99 years using equation 4. This method allows for flexibility in cases where the Medicare data are not available in a timely fashion. In these cases, Medicare data for the previous year can be used to calculate k_x values. Finally, ${}_∞q_{100}$ is set equal to 1.0 because all will die at some point in this open-ended age interval. Once q_x is obtained for each single year of age, the other life table functions may be easily calculated.

Survivor function (l_x)—The life table radix, l_0 , is set at 100,000. For ages greater than 0, the number of survivors remaining at exact age x is calculated as

$$l_x = l_{x-1} (1 - q_{x-1}) \tag{6}$$

Decrement function (d_x)—The number of deaths occurring between age x and $x + 1$ is calculated from the survivor function.

$$d_x = l_x - l_{x+1} = l_x q_x \tag{7}$$

Note that ${}_∞d_{100} = {}_∞l_{100}$ since ${}_∞q_{100} = 1.0$.

Person-years lived (L_x)—Person-years lived for ages 1 to 99 is calculated assuming that the survivor function declines linearly between age x and $x + 1$. This gives the formula

$$L_x = \frac{1}{2} (l_x + l_{x+1}) = l_x - \frac{1}{2} d_x \tag{8}$$

For $x = 0$, the separation factor f is used to calculate L_0 .

$$L_0 = f l_0 + (1 - f) l_1$$

${}_∞L_{100}$ is calculated by surviving the life table cohort from age 100 using equations 4, 5, and 6 until L_x at these ages is essentially zero (somewhere between ages 110 and 120). q_x for these ages can be extrapolated from the Medicare data using equation 4. However, k_x values must be estimated for these ages. k_x can be modeled as a linear function of age

$$k_x = k_{85} + (x - 85)s \tag{9}$$

where s is the slope of the change in k_x by age and k_{85} is calculated as $[\ln(q_{88}/q_{81})]/7$ in order to minimize the effects of random fluctuations (16,21). s can be obtained by treating equation 9 as a linear regression model. Calculated values for s are shown in Table IV. The

Table III. k values by age, race, and sex based on insured Medicare data: United States, 1999–2001

Table IV. Slope of the change in k values (s) by age, race, and sex

Race and sex	s
Total, both sexes	-0.001370
Male	-0.001496
Female	-0.001487
White, both sexes	-0.001460
Male	-0.001602
Female	-0.001584
Black, both sexes	-0.000761
Male	-0.000848
Female	-0.000842

predicted values for k_x are then used to calculate q_x above age 100 using equation 4. The corresponding L_x values for ages 100 years and over are then summed to give ${}_{\infty}L_{100}$.

Person-years lived at and above age x (T_x)— T_x is calculated by summing L_x values at and above age x .

$$T_x = \sum_{t=0}^{\infty} L_{x+t} \quad [10]$$

Life expectancy at age x (e_x)—Life expectancy at exact age x is calculated as

$$e_x = \frac{T_x}{l_x} \quad [11]$$

Abridging the complete life table

An abridged or collapsed version of the complete life table can be easily calculated in which life table functions are shown for 5-year rather than single-year age intervals. It is often desirable to

summarize the life table and save space when publishing life table data by single years of age. The abridgement of the complete life table is simplified by an important property of three of the six life table functions. The l_x , T_x , and e_x functions describe exact age x (i.e., the beginning of the age interval x to $x + n$ (n denotes the length of the age interval for 5-year age intervals $n = 5$)). Life expectancy at age 20 (e_{20}), for example, has the same value regardless of whether the age interval is 20–21 years or 20–25 years. Thus, the values l_x , T_x , and e_x can be extracted at 5-year intervals from the complete life table and placed into the abridged life table (compare l_x , T_x , and e_x in Table V with the same functions in Table 1). It is also illustrative to compare values for e_x and l_x in Tables A and B with their corresponding values presented in Tables 1–9. The q_x , d_x , and L_x functions, in contrast, describe the age interval x to $x + n$. In fact, for abridged life tables, the notation for these functions is different (${}_nq_x$, ${}_nd_x$, and ${}_nL_x$). Thus, ${}_5q_{20}$ is the probability of dying between ages 20 and 25 years and will obviously be somewhat larger than q_{20} , the probability of dying between ages 20 and 21 years. Taking this into account, ${}_nq_x$, ${}_nd_x$, and ${}_nL_x$ must be recalculated in the abridged life table. It is simplest to begin with ${}_nd_x$. The calculations are made for all but the final age interval as follows:

$${}_nd_x = l_x - l_{x+n}$$

$${}_nq_x = \frac{{}_nd_x}{l_x}$$

$${}_nL_x = T_x - T_{x+n}$$

Note that for the open-ended interval, ages 100 years and over: ${}_{\infty}d_{100} = l_{100}$, ${}_{\infty}q_{100} = 1.0$, and ${}_{\infty}L_{100} = T_{100}$. Table V shows each of the life table functions for the 2004 U.S. total population abridged from Table 1.

Table V. Life table for the total population: United States, 2004

Age	Probability of dying between ages x to $x+n$	Number surviving to age x	Number dying between ages x to $x+n$	Person-years lived between ages x to $x+n$	Total number of person-years lived above age x	Expectation of life at age x
	${}_nq_x$	l_x	${}_nd_x$	${}_nL_x$	T_x	e_x
